Canard Pushers from 1 to 82

Table of Contents

Canard Pushers from 1 to 82

Notes on "THE ELECTRONIC CP", by Stet Elliott

"THE ELECTRONIC CP" is a set of computer files consisting of all Canard Pusher (CP) Newsletters published by Rutan Aircraft Factory. The set includes all CPs from the first one published in May 1974, to number 82 published in October 1995. There have been newsletters published after that date, however I do not intend to convert them to digital format.

Every effort has been made to ensure accuracy in this product set, but ACCURACY IS NOT GUARANTEED! If you are building a Rutan design, you MUST NOT rely on "THE ELECTRONIC CP" as your only source of current information. You will also need the printed copies of the CP's because "THE ELECTRONIC CP" does not contain the required illustrations, photos or graphs you will need to properly build and fly a RAF design. Obtain printed copies of Canard Pusher newsletters from Rutan Aircraft Factory, or another builder. You may make copies of another builder's CP's. This is approved and encouraged by RAF, and is so stated in each recent newsletter.

VARIVIGGEN NEWS NO. 1 May 74

RUTAN AIRCRAFT FACTORY/P.O. BOX 111/VALLEY CENTER, KS. 67147

THE NEWSLETTER staff has finally organized: Burt Rutan, Editor-in-Chief; Carolyn Rutan, Proof Reader. This, being the first newsletter, will be mailed to all holders of VariViggen Tech. Reports and Plans. Future newsletters will be mailed only to those who actually plan to build an airplane and who have an Aircraft Serial Number assigned.

This is your newsletter, the sole purpose of which is to aid in your construction projects through exchange of information. Please feel free to send progress reports, comments, or photos of your project for printing in future newsletters.

ACTIVITY at the RAF - Carolyn and I have spent a busy Fall and Winter preparing the plans and getting them mailed. My apologies to those who waited several months. Our prototype, N27VV, has passed her 300th flight-hour, and our latest inspection and relicense revealed only that she needed new tires and brake pads. The low maintenance requirements have been very pleasing. Check around and see how much flying most homebuilt prototypes see in their first two years! We took several trips this winter - see May '74 "Sport Aviation". N27VV has given two airshow performances so far this year and we have approximately eight more on the schedule for this season, including Oshkosh, July 31-August 6, and Brantford, Ontario, August 10 and 11. Sales of plans now total 190, and 53 builders have already returned their "Page Two", requesting a serial number and indicating that they plan to build an airplane. Of these, 41, plan to build theirs similar to the prototype or with minor modifications, and the rest - wow! We will see some very interesting flying machines! To get on the Sport Aviation list of Aircraft Under Construction, I urge you to notify EAA Headquarters of your project. To the builders, I'm enclosing a complete list of all present builders (by Aircraft Serial Number), their addresses, and any major modifications they are considering. I will mail the list to other plan holders only if they return "Page Two" indicating they intent to build an airplane. This list will be updated each Newsletter.

PLANS Changes - I'm very happy to report that there have been very few corrections reported.

1. Material was omitted on F13; it is 1/8" plywood.

2. The fixed trim tabs, which are discussed in the Tech Report, were omitted. They should be installed on each elevator to improve trim characteristics (speed stability). Each tab consists of a Balsa wood airfoil epoxied to two booms (1/4" hardwood dowels) which are epoxied into 1/4" slots notched into the trailing edge of the elevator. I have noted no performance loss due to the tabs. The booms increase the tabs effectiveness at high speed and prevent the tab from reducing maximum elevator lift. **SKETCHES OMITTED**

3. The Tech Report refers to the propeller size as 70Dx67P. Performance on 150 HP is best with a 69Dx64P or 69Dx65P prop as shown in the plans.

4. Zounds!$#, don't plug in your angle-of-attack indicator! I slipped a decimal point on a resistance (pg 43 of Plans). The revised schematic shown, also includes the trimpots I have in my airplane to allow fine calibration. This is identical to the system in N27VV. This system can also be used for the car-top wind tunnel shown in the Tech Report. **SKETCH OMITTED**

5. The sharp eye will note the slant in the side of F121 bulkhead on pg 19 (B.L. 12.1 to B.L. 12.25). This is because the bulkhead slants backwards (see side-view) while the fuselage is getting more narrow (see top-view). No errors here; just a clarification of the reason for the slant.

6. NG35 is an 8" Scott tailwheel assembly, not 9".

VVN1, Page 2

ALTERNATE Source for Epoxy - I've found another wood bonding epoxy that can be substituted for the Epibond. It's a 50-50 mix and, thus, is less critical to mix than the 10-to-1 Epibond. It's Bond Master M666 by National Starch & Chemical Co., 653rd Ave., N.Y., N.Y. Weibe Wood Products, 311 S. Kansas, Newton, Ks., 67114, sells it at $13. for two quarts. I've seen its excellent results in several wood aircraft.

ENGINE Selection - Alot of you indicate preference for larger engines. Frankly, I'd like to have an 180 hp O360 in mine, but I do not recommend the 200 hp Lycoming: the extra weight would create a tailheavy condition that would require some redesign. The same is true for a metal prop or constant speed prop. As many are now finding in other applications, the modern wood prop is unbeatable for fatigue-free safety.

FULL-SIZE Drawings - I received a question as to why all the drawings for ribs, etc. are not full-size to allow tracing to the part. The answer is because so many of the ribs, etc., are so long, that they won't fit any convenient paper size, and that paper that long, can shrink and thus effect the size of the part. If you use the following hints you will find that converting the scaled-down drawings will be a very small percentage of the work required to build your aircraft:

Do not draw the part full size to transfer to the material; transfer the dimensions directly to the wood or metal (ball-point pen on wood; BIC Banana on metal). Have a wife or friend read the dimensions from the drawing or grid while you use a scale to plot them on the material. This is much faster than looking back and forth and eliminates errors. Buy a Stanley metal tape, rule no. B61-112Y. This is a 12 foot retractable tape-rule with graduations in tenths of inches, not 1/16ths. That tool alone will save you many hours of conversions.

MACHINED Parts - A question has come up as to whether the machined parts will be available. If I can receive orders for 25 or more sets,

the handling and shipping costs can be justified. The set would include

(8) WA5 taper pins	(1) NG32, NG33, NG34 assembly (welded, heat-treated & chromed)
(1) RM5 screwjack	
(1) RM6 threaded tube	
(2) V1 plugs	(1) NG37
(1) NG1 spool	(2) MG12
(1) NG28	(2) MG15
(1) NG29	(2) MG19
(1) NG30	(2) MG30
(1) NG31	(2) MG35
	(1) MG42

Let me know if you would consider buying some or all of these. The price would be more than it would cost if you had a good friend with a lathe, but considerably less than if you took the drawing to the local machine shop. I'll definitely have F23, F25, F27 and F28 available by December 1974 and the cowling shortly thereafter.

PHOTOS - I'm also considering making available photographs, if there is demand enough to get a low price. Let me know if you would be interested in

Set #1 8x10 Color - Top quality, suitable for framing:
1 inflight shot
1 ground shot with Carolyn
1 shot showing cockpits with canopies open.
Approximate cost, $14. plus mailing cost.

Set #2 4x5 Black & White glossy:
4 different inflight shots
4 different ground detail shots
4 different cockpit shots
Approximate cost, $5. plus mailing cost

VARIVIGGEN PATCH - The symbol on the cover, we selected as the official VariViggen patch. Our distinctive plan view identifies us without need for words! Look for it at Oshkosh. Sew-on jacket patches will be available.

ITEMS - for Future Newsletters: Cockpit head system, stowable ladder I use for front seat entry, improved carb heat muff design, complete treatment process for sealing plywood and for exterior finishing, additional hints on electrical system, etc., etc.

QUESTIONS - I can answer your questions, etc., promptly only if you include a self-addressed, stamped envelope.

ORDER BLANK FOR MACHINED PARTS OMITTED

VARIVIGGEN NEWS NO. 2 Oct 74

Published quarterly by Rutan Aircraft Factory
Burt & Carolyn Rutan
Building #13, Mojave Airport
P.O. Box 656, Mojave, CA 93501

ACTIVITY at the RAF - This is the first opportunity we've had to inform everyone of our move. We have a new facility at the Mojave, California Airport where we are supporting VariViggen builders. We left Kansas in June and spent most of July in southern California looking for a home for the RAF. We then took N27VV on a 4500-mile trip which included the Oshkosh EAA convention (N27VV participated in the evening airshow and won the "OUTSTANDING NEW DESIGN" trophy this year), a visit with Ken and Margaret Ashdown (VariViggen builder S/N 069) on the beautiful island of Manitoulin in Ontario, Canada, Airshow appearances at Brantford, Ontario where we were the guests of the fine people of EAA chapter 115, stops in Kentucky, Indiana, Missouri, Kansas, and finally our big move to California, arriving in Mojave the first week in September. N27VV performed well despite the 110-lb baggage load on most of the trip and the 10,500-ft density altitude takeoff at Flagstaff, Arizona!

We made up "VariViggen Builder" badges for those who were at Oshkosh. We were pleased to see more than 40 builders during the week as well as six more at the Brantford show. Back-seat riders at Oshkosh included Fred Weick (Eurcoupe designer), Charlie Schuck (FAA), Harold Best-Devereux (EAA, Europe), Sheldon Gallager (Editor, Popular Mechanics), Peter Lert (Air Progress) and many of the builders. We flew two photo flights in which we posed for air-to-air shots in formation with Dick Curtis's Curtis Pusher Replica at 50 kt! Those photos should show up in magazines and the EAA film.

Even though the VariViggen had been to California twice before, we couldn't wait after arriving to Mojave for the first chance to really demonstrate her flying ability to the multitudes out West. The next weekend, September 7-8, was the EAA Western Fly-in at Porterville, CA. The following excerpt from the Bakersfield, EAA Chapter 71, newsletter written by Denny McGlothlen tells it all.

"The star of the show was Burt Rutan with his "VariViggen", Boy this bird really turned me on. I was out on the runway when Burt flew in the airshow, and seeing the VariViggen make the low speed sharp turns right at lift off, well an airplane just isn't supposed to do such things but this one sure will. I can see that this is going to be a very much built airplane in the EAA ranks."

The VariViggen succeeded in awing the crowd there and also won the "Most Popular" trophy, the "2nd Monoplane" trophy, and the 1st place cash prize for the spot landing contest. The VariViggen has won every spot landing contest it has entered. Due to the fantastic low speed maneuverability and visibility you can use quick tight turns on short final to set up the correct height and speed for the accurate touchdown. The 2nd place-winner at the Beatrice, Nebraska contest just shook his head and said, "That's no fair; That's not an airplane!"

We have two more airshows and a magazine article commitment within the next two weeks. After that we plan to remove the old cowling, give the aircraft a good inspection (she now has 400 flight hours) and install the new design cowling with prop extension. When testing is complete on the cowling we will begin cowling production.

RAF BUSINESS - Yes, we are now conducting a full-time business primarily to support VariViggen builders. Our facility on the Mojave Airport (100 yards S.E. of tower building) consists of an office and shop sufficient to allow us to provide VariViggen components, related engineering support for VariViggen builders, technical and educational material (the car-top wind tunnel project is aimed primarily at high schools and colleges), and engineering analysis/test consulting. Refer to the first edition of our CATALOG, included with this newsletter for detailed description of all products. The last page will be revised periodically and mailed to all builders.

We now see an important need for a periodic newsletter, complete enough to give all the information to builders that can assist them in their projects. Future newsletters will include essentially the same format information and photos as this one, with more builder-submitted information as it becomes available. All suggestions are considered - Remember this is your newsletter. Due to the fact that the plans have (and will be) marketed at a relatively low cost, builders are now being asked to share the continuing cost of research writing, setup, printing, and mailing the future newsletters on a yearly subscription basis. Refer to the CATALOG for the cost and publish dates. Newsletter #2 is provided free to all plans and TR holders. Future ones can only be sent to paid up subscribers. We will continue to provide the updated list of VariViggen builders only to those who have returned their plans "page two" and have received an Aircraft Serial Number. We keep individual correspondence files of builders with S/N's, which now totals 128 builders.

PLANS Changes - It has been four months since the last newsletter and many of the builders are well into their construction projects, so we have quite a few corrections/improvements to note. This section will provide changes, not only to the plans, but to the Tech Report and Owner's Manual as well. Changes will be classified as follows:

- MEO - Minor error or Omission.
- OPT - Optional Improvement.
- DES - Desirous Change - Does not necessarily effect flight safety but should be incorporated to improve the aircraft or correct a fault.
- MAN - Mandatory Change - Change must be incorporated as soon as possible as safety of flight is affected.

Remember, all mandatory changes are Air Mailed immediately to all newsletter subscribers.

CATEGORY	LOCATION	CHANGE
MEO	PL pg 59	Part No. of 8" Scott tail wheel assy omitted. NG35 is Scott #3200. Channel shaped plate is furnished

		with V-NGSA assy purchased from RAF.
DES	PL pg 1&2	Change RAF address: Box 656, Mojave, Ca. 93501
DES	PL pg 3	On weight & bal chart change 115 hp to 125 hp.
MEO	PL pg 5	Change number of AN3-14A bolts from 3 to 8. Change AN115-16 (16) to AN115-3 (3).
MEO	PL pg 11	3rd column, 2/3 down F.S.137 should be F.S.37.
DES	PL pg 13	I'm told that solid rod gives better antennae performance than tubes. Use 1/8" alum welding rod or some alum clothes line available at any dept. store.
MEO	PL pg 14	Clarification - The C12 belcrank bearing rivets to outboard side of C9.
MEO	PG pg 20	F30 & F29 identification is reversed on flat layouts.
MEO	PL pg 21	Capstrip detail W.L. 0.1 should be W.L. 0.0.
MEO	PL pg 25	SPAR F change WS3 to W3. Two places.
MEO	PL pg 26	SECTION L-L change 57 deg to 54 deg.
MEO	PL pg 27	Right center. Change 83 deg to 173 deg.
MEO	PL pg 31	WA3 Omitted dimensions. Left two holes are centered. Other six holes evenly spaced & 0.31" from edges as shown.
MEO	PL pg 36	Tolerance on all control travel is +- 3 deg, except reflex travel which is 0 to 1 deg up (when down) and 7 to 8 deg up (when up).
MEO	PL pg 37	EC1 can be made easier & stronger with the legs overlapped or with doubler plates rather than butt welded.
DES	PL pg 42	RM5 change coarse thd to course double advance thd (for faster reflex travel).
MEO	PL pg 45	Pivot detail F14 should be F31.
MEO	PL pg 46	NG32 change to .063 wall to .065 wall. NG1 1/16" hole for cable. Change to #50 drill hole.
MEO	PL CH 8,10	Clarification on wing attach assemblies. Be careful when cutting tapers in steel straps for WA5. There is a lefthand & righthand part to put the 5/16" holes in lower WA2 fittings on top.
DES	PL pg 50	MG2 5.1R should be 2.6R. MG5 1.63D should be 1.75D. MG11 1.7D should be 1.75D. MG4 "to fit MG12." The preferred method is to first drill MG4, clamp to MG12 then use MG4 as a drill guide to drill MG12.
MEO	PL pg 51	MG42 add the #50 drill cable hole as in NG1.
DES	PL pg 46	Strut assy. To allow improved strut lubrication, eliminate upper O-ring (2.8" from housing bottom) and move lower O-ring down .4" to within 0.1" of scraper. If you have already cut the two O-ring grooves, that's Ok; just cut the new lower one and leave the other grooves empty.
MEO	PL pg 53	Table at right. Switch No. 2. Change "overridden" to "not overridden."
MEO	PL pg 55	2nd column, 1st row. Add WR42 after WR32.
MEO	PL pg 58	NG21 Change F14 to F31.
MEO	PL pg 59	NG30 Add "any type steel."
MEO	PL pg 57	SA6 Change AN115-16 to MS20115-3 or to AN115-3. (Same thing).

OPT	PL pg 60	Static holes on both sides are optional. One side only is ok with a very minor error due to side slip (about 0.5 kt per deg).
MEO	PL pg 3	Lower left. Change 134.1 to 132.1.
DES	TR Cover	Change address & move nosegear back 6" on 3-view.
DES	TR pg 2	Change address. Change reference to "pk2" to "Plans."
MEO	TR pg 5	Change empty weight to 950 lb. Change limit "g" to 5 g. Ultimate is 7.5.
MEO	TR pg 5	Range with fuselage tank 375 mi. 555 mi. with added 12 gal long range tank.
MEO	TR pg 5&7	Change 300 ft to 400 ft.
MEO	TR PG 7	Change 85 KT TO 80 KT.
MEO	TR PG 12	Add weight = 1500 LB to upper graph.
MEO	TR PG 23	Delete all reference to Bede. Change Newton to Mojave. (805) 284-2645. Delete answer about kit, refer to RAF CATALOG.

NOTE: I strongly suggest that you write all changes into the plans from this list. Thus your plans will be updated even if you lose your newsletter and will contain no erroneous information.

MORE BUILDING TIPS

1. You don't need to strain your eyes on the grid on the vertical stabilizer ribs to get them cut out exactly the right size. Cut the top and bottom the correct size and make the others oversize. After they are mounted on the spars and the glue is dry make a 4-foot long sanding block out of a wood 2x2 with sandpaper glued along one edge. Run the block (held vertically) over the ribs to bring them down to the spars and into line with the end ribs. That tool can also be used to taper the top capstrips on the inboard wing and the fuselage formers to fit the skin.

2. Remember to get help on plotting the grid-drawn items up to full size. One person to read x & y dimensions from grid and one to plot (2 rulers help) directly on the wood. Several builders reported that they made all formers, canard ribs, inboard wing ribs and vertical stab ribs in less than 1 1/2 days work; a reasonably small percentage of the total job. Carrol Holzworth (S/N 2) reports that he found a large sheet of thin plastic, drew 1" grid lines on it, then used it as a full size grid to punch through to mark the parts. Be sure you are using the decimal 12" rule and tape measure, fractions are for carpenters!

3. One builder wanted to know why there are more and larger bolts on WA2 than on WA3. The reason is they are sized for bearing on the wood spar vs aluminum spar.

4. When drilling through the wood spar for the wing attach fittings use the following procedure: Clamp only the forward fitting in place. Be sure it's at the correct W.L. and B.L. Square the drill as well as possible (use a long drill bit and use a square) and drill only one hole. Then clamp the rear fitting on, installing a bolt in the first

hole. Now drill all holes in the front only drilling 1/2 way through the spar. Then drill about 2/3 through from the rear to complete the holes. On final installation be sure to fill the holes with epoxy to take up any voids due to hole misalignment. The epoxy is stronger than the wood and will assure full strength even if there is a little slop in the holes.

5. Glue the building jig to the floor to prevent shifting during construction. Install a tight wire at W.L. = 0 and B.L. = 0 for use as a reference in measuring. The wire is stretched along the jig, attached forward of F.S.20 and aft of F.S.200. A tape rule and good carpenters level can thus locate any B.L. and W.L.

6. Be sure you are using a good epoxy glue (see plans and Newsletter #1) coat both parts and put on enough for a generous fillet. Capstrips are not required on the canard or vertical stab. It's probably a good idea to use 3/32" or 2 1/2 mm hard birch ply on the canard top skin. This is not needed for any flight loads but the canard is used for handling the airplane on the ground. With the stick back you can reach over the canard and grab the canard trailing edge (not elevator) to pull the airplane. If you're already sheeted with 1/16" ply you may consider one light layer of fiberglass on top.

7. After trimming the canard skin adjacent to C8 spar, not too much overlap is left on the bottom. This can be reinforced with epoxy and cloth strips on the inside (Dynel, fiberglass, or even cotton). Don't do this everywhere, though, it can build up excess weight.

8. Charles Allen (S.N 047) substituted .063 4130 bent angles for C10. This is fine here, but the extra stiffness of extruded aluminum angles in most other places is required. 6061 T-6 can be used for C9 and E6.

9 I noted the bottom of the canard and elevators to provide inter-bay drainage and only used 3 drain holes on each canard and each elevator.

10. Wayne Koch (S.N 009) build a Gilliom 18" bandsaw and 6" sander from a kit. They look like quality tools at a real low price. I was impressed with his, so I'm building my own. Write for their catalog, 1109 N. 2nd St., St. Charles, MO 63301. The bandsaw needs to be modified to provide a slower speed for steel cutting.

SHOPPING - Here are a few helpful sources we've found or have been notified of.
1. Western Ply & Door still has good prices on the birth ply (See Chap 2). 50" x 50" sizes.
2. UNIVAIR, Rt 3, Box 59, Aurora, CO. 80010 has rebuilt Scott tailwheel assy #3200 for $70.00.
3. Harbor Sales, 1401 Russell St., Baltimore, MD 21320 has an excellent lightweight plywood (A/B OKOUME) in the thicker sizes (5/32" & up). Their 5/32" is light enough to be a substitute for birch 3/32". It is too soft to substitute where hard birch is called out. Send for their price list.
4. Spencer Aircraft, 8725 Oland Ave., Sun Valley, CA 91352 has good prices on hardware, I'm told.
5. Ask questions at your local EAA chapter meeting.
6. These outfits have catalogs with a very wide variety of needed parts, the first one is an absolute must: Aircraft Spruce & Specialty,

Box 424, Fullerton, CA 92632; WAG Aero, Box 181, Lyons, WI. 53148; Aircraft Components, Northshore Dr., Benton Harbor, MI 49022.

FLASH - "FLYING" MAGAZINE FLIES THE VARIVIGGEN - Peter Garrison of "Flying" magazine conducted a flight evaluation of the VariViggen for an upcoming article in "Flying," the largest general aviation magazine.

PARKING - Without pilot or copilot the cg is very near (slightly aft) of the main wheel location (with weight on the main gear its reaction moves aft of the no-load position shown in Chapter 19). Thus when the pilot gets out, he lets the aircraft down on the aft skids. At first we were ashamed of this tail-sitting attitude and would immediately tie the nose gear to a tiedown or install an aluminum tube tripod under one skid whenever we parked. I don't do this anymore for the following reasons: 1) sitting on the skids, the center of pressure is well centered and the aircraft will take winds from any direction with little weathervaning or upsetting tendency common to the conventional parked aircraft, 2) when parked in a hangar even a low wing aircraft will overlap all the way to the fuselage and thus a VariViggen will take up considerably less room than even smaller homebuilts (I've put it in many hangars after the owner said "sorry we're full," without even moving other airplanes!)., 3) this attitude allows more convenient preflight inspection of fuel, oil, landing gear and pulling the prop through, 4) baggage loading, fuel and oil loading is convenient while on the tail, 5) it is very easy to pull the nose down by the canard tip, step to the ladder and get in when ready for ingress, 6) we consider it a "status symbol" - just one other thing no other plane on the field can do! However, for an airshow, in order for people to more easily inspect the cockpit, we either tie the nose gear to a tail tiedown rope (VariViggens park backwards, too!) or retract the nosewheel only (pull the main gear breaker) and set it clear down on its nose. Thus, the canard is an excellent seat for four to watch the show!

ENGINE Selection - Since I mentioned I would like to have 180 hp in Newsletter #1, alot of you have thought it was for more speed. Not true, considering 75% power cruise, speed would only increase 10 mph with 180 hp. The main reason would be for better rate-of-climb, particularly at high altitude. Remember, low aspect ratio means lower climb performance. A VariViggen will not climb as well as a conventional aircraft with equal cruise speed and hp/weight ratio. Those that want better high altitude climb performance and want to use a heavier engine or constant-speed prop will find the airplane tailheavy and for that reason I have not recommended them, due to the terrible requirement for lead in the nose. There is a better solution, however, that can eliminate this problem. I used this solution when I found my partially completed airplane to be tail heavy. The original design had a shorter wingspan. I increased the span of the outboard wing panels. This moved the allowable cg range aft, thus solving the problem without lead. A disadvantage is a slightly reduced g-capability. If you are interested in using a constant-speed prop or heavier engine, send me the weight, length of engine, and weight of the

prop. I will then calculate for you the amount of extension to the wingtip, show how to make the extension and calculate the amount of reduction in allowable 'g'. Please also include $6.00 as consulting fee for this design change. This can only be done up to a point at which the control power of the canard is reduced and the overall cg range is too small. While this solution is better than lead nose weight, I still recommend 150 hp (180 hp for short airstrips or high density altitude flying) and a modern light weight wood prop.

MODIFICATIONS - As you know, it has been our policy to not be adverse towards those who want to modify the aircraft. We have had this policy mainly in the interest of promoting education and design progress. However, we have seen some examples of modifications, even some under construction that will result in disappointing performance and in some cases unsafe flight characteristics. In all cases those individuals designed their modifications by aesthetics and by eyeball rather than by valid engineering calculation supported with appropriate tests. In most cases, when I was able to point out the disadvantages and calculate the effect on performance and stability, the author of the change decided to stick with the plans. One builder doubled the rudder area and didn't even know that that would reduce overall directional stability due to rudder float.

I must modify my policy to point out that I am not adverse to anyone modifying the airplane that is qualified (or finds qualified help) and is willing to conduct the analysis and tests required to verify the modification before flying his aircraft. I am very adverse to those who may give all the rest of us a bad image by building a "VariViggen" that either has poor performance or contributes to an accident statistic under the name VariViggen.

A plans-built aircraft has good utility and excellent flying qualities. Modifications that add weight, be they as subtle as extra heavy gussets everywhere or fiberglass over the wood skin, or more substantial like 70 gallons fuel or four place, etc., etc., can result in very disappointing climb performance at high altitudes. Our experience in flying N27VV over 400 hours in all kinds of flight conditions, runways, weather, density altitudes, etc., is very valuable and we have found that due to the low aspect ratio (necessary for optimum low speed flying qualities) the airplane should have a lower weight-to-power ratio than conventional designs. You cannot expect to carry four people and more fuel adequately from Albuquerque in the summer unless you use at least 200 hp.

You cannot expect the same safe flying qualities if you stretch the nose sever feet for "looks." This would decrease stability and actually slow down the aircraft! You cannot just assume that a beautiful flush inlet three inches from the top of the wing will provide adequate cooling. My measurements during development of an oil cooler system showed terrible pressure recovery during low speed.

I should point out that because with a canard aircraft both surfaces are lifting wings (the canard actually has a much greater wing loading than the main wing) their size, position, interference with each other, high lift devices, etc., have a very important effect on the cg range, the flying qualities, and low speed performance. Their design is far

more critical than with a conventional aircraft with one main lifting wing (sized for performance, etc.) and a tail sized

---

merely to provide adequate static margin and sufficient cg range. For example a formula-one racer has an extremely small tail - but it can be designed for one cg only and still provide adequate stability and sufficient control But if it were a canard, the designer would have much less room for change, to provide a large flight envelope (speed range and maneuverability) even for one cg.

Therefore I am unable, without conducting the appropriate test to answer a question like "is it ok to move the canard down eight inches to clear my extra radios in the instrument panel." I am not adverse to you making the change, however, if you are willing to conduct the test and verify its satisfactory result. The car-top wind tunnel system which will be available this December is an excellent method, others are also valid.

Remember, this aircraft was not developed by "guess work" but by a very careful design-test program. Small changes can be full of "surprises." If you modify an aircraft, when it is ready to fly, you are an experimental test pilot, not a production test pilot - be prepared to accept the full responsibility to safely plan and conduct exploratory testing and critical flight envelop expansion - for there are no proven limits on your airplane.

I don't mean to inhibit progress, only to promote valid development. In this way we are also promoting education, which is what EAA is all about!

NASAD - The VariViggen plans have been submitted for approval by the National Association of Sport Aircraft Designers. Several areas of information are required that were being reserved for the VariViggen Owner's Manual. This information is being distributed to all plans holders now in order to qualify for NASAD approval before the complete Owner's Manual is published. The information in the Owner's Manual will be more detailed and will include information in several other areas (see Catalog).

VARIVIGGEN AIRCRAFT
MAINTENANCE/INSPECTION/OVERHAUL/CHECKLIST
MAIDEN FLIGHT PROCEDURE

MAINTENANCE/INSPECTION

Wood Structure - Wood structure, properly sealed with the epoxy specified or with a good grade of varnish, will provide years of service with no maintenance, especially when hangared. Periodically check all visible surfaces for cracks or ships in the finish that indicate either degrading protection or internal damage. Check that all moisture drains are open. Remove the outer wing panels once per year to inspect inboard wing internal structure through WR46 rib.

Metal Structure - Periodically inspect rudder and outer wing panels for skin buckles or loose rivets that may indicate internal damage. Check that all moisture drains are open (none required on foam filled ailerons). Inspect outboard wings for internal damage and corrosion through ribs with panels removed once per year.

Plexiglass - Cracks up to three inches long should be stop-drilled 1/4" outside of the visible end with a 1/8" dia drill. Larger cracks require replacement (N27VV has had no cracks).

Mechanical Components - All controls and reflex/gear pivots that are sealed bearings or oilite bushings require no lubrication. Check periodically for any excessive slop or binding. Check all cables annually for any signs of fraying or wear. Replace any frayed cable. Grease main gear, external gears, reflex screwjack, NG23, MG16 bushing, and MG31 zerks with automotive grease every six months. Periodically check main gear shock doughnuts and all tires for excessive cracks. Inflate main gear tires to 36 psi and nose gear tire to 40 psi. Periodically clean nose gear shock strut and service as shown on plans, page 45, once per year. Check brake fluid level and brake puck wear twice per year or every 50 hours of flight time. Check all landing gear, engine mount, and control system structural parts for damage or cracks each 50 hours of flight time. N27VV required only routine maintenance and one brake shoe and tire change in its first 300 hr/2 years.

Electrical - Check for loose or chafing wiring every 50 hours flight time. Follow manufacturer's recommended maintenance for battery.

Engine, Propeller, & Instruments - Follow manufacturer's recommendations.

OVERHAUL

Engine, Propeller, & Accessories - Follow manufacturer's recommendations.

Gear & Reflex Motors (MG39, NG4, & RM9) - Replace every six years if aircraft is hangared and every three years of not hangared.

Wheels & Brakes - Follow manufacturer's recommendations.

CHECK LIST

Preflight

1. Ignition - off
2. Remove gust locks
3. Remove tiedowns
4. Check control surfaces
   (freedom & security)
5. Check landing gear & tire
6. Check fuel & oil quantity
7. Under cowling - nothing

hanging or dripping
8. Drain strainer
9. Prop (nicks & security)
10. Pitot static - clear
11. Gear handle down
12. Master on - check reflex operation & instruments

Engine Start

Follow manufacturer's recommendations

Before Takeoff

1. Fuel - on
2. Mixture - rich
3. Mags & carb ht
4. Trip - T/O
5. Reflex - 8 deg
6. Ammeter - chg
7. Gear - handle dn, 3 green lights
8. Controls - free
9. Engine inst. - green
10. Circuit breakers
11. Harness - both seats
12. Canopys - locked

Before Landing

1. Mixture - rich
2. Carb ht - A/R
3. Reflex - 4 to 8 deg
4. Gear - dn, 3 green lights, visually check mains
5. Airspeed 65 to 75 kt on final

Securing

1. Avionics - off
2. Master - off
3. Mixture - cutoff
4. Ignition - off
5. Gust locks - on
6. Tiedowns

MAIDEN FLIGHT PROCEDURE

Ground Tests - Run engine on ground at lease one hour. Check for sufficient fuel flow at full throttle and minimum fuel quantity. Taxi enough to thoroughly check engine, brakes, controls, landing gear, and to become thoroughly familiar and comfortable in the cockpit. Recheck weight and balance (see operating limitations).

High-Speed Taxi - Weather - smooth air, no crosswind. Runway requirements - smooth, at least 4000 ft for initial tests. Reflex - 8

degrees. Make several runs as follows to speeds of 40 kt, 45 kt, 50 kt, 55 kt: Accelerate to aim speed; reduce power to maintain speed. Lift nose wheel off about one ft above the ground, check directional and pitch control, rock wings (with mains still on the ground) to get the feel of roll control (nose may not rotate at 40 kt). When you feel you can comfortably control pitch attitude up to one to two ft nosewheel height, you are ready for lift-off. Accelerate to 60 kt, reduce power to about 1/2 throttle, rotate nose and fly down the runway at an altitude of several feet. Reduce power very slowly to idle once airborne (slowly, so you don't have to adjust for abrupt pitch trim changes, if any). The airplane exhibits a pronounced ground effect and may float a long way down the runway. Its best not to make a "full stall" landing (aft skid clearance), just lower it to the runway. Ask yourself - is the airplane out of trim directionally or in roll? If not, you're ready for the first flight.

First Flight - Once the lift-off and flight down the runway is accomplished, the hard part is over. The actual takeoff, full flight, and landing are much easier. I still recommend smooth air and a large smooth runway. The following is a description of the prototype's (N27VV) first flight: "As the Cessna 172 chase plane maneuvered into position, I started my take-off roll. Take-off (at 50 kt) and climb (at 80 kt) were normal and a very strange feeling came over me as I cleared the end of the runway. The air was absolutely still and there I was climbing straight ahead. I had waited a long time for this moment, but somehow it felt like I was on my first solo. I had to rock the wings to convince myself I was really flying. I leveled off at 1500 ft AGL and performed some stability checks - static and dynamic and pleased with the results proceeded to do sideslips and maneuvering turns. I set the reflex at several positions and slowed up to near full aft stick to check low speed handling. Again the aircraft felt solid, while still responsive - particularly in roll. So much for the "work", I moved in close to the Cessna for some pictures, then made a low pass down the runway and landed just a sunset after 50 enjoyable minutes of flying." Best final approach speed for first flights is 75 kt.

DO NOT forget to send us your change of address if you move. If you have a question that requires our answer, send a self-addressed, stamped envelope. Be sure to send any comments or suggestions for the newsletter. Also send us your builder tips and photos. Items to be covered in future newsletters: details on new cowling, long range fuel tanks, alternative aileron construction eliminating foam, cabin heater, ingress ladder, improved carb heat muff, external wood finishing procedure, and anything you suggest!

VARIVIGGEN NEWS NO. 3 Jan 75

Published quarterly by Rutan Aircraft Factory
Burt & Carolyn Rutan
Building #13, Mojave Airport
P.O. Box 656, Mojave, CA 93501
(805) 824-2645

THE VARIVIGGEN program is now in high gear! We are very pleased to see the great number of excellent projects under construction. As of this writing we have received the plan's "page two" from 218 builders indicating that they are building or are planning to build. (Those of you with aircraft serial numbers have the updated builders list enclosed with this newsletter.) We estimate that about 150 projects are now in the construction stage.

The following are photos of projects sent to us. We encourage all of you to send photographs for the newsletter (black & white), also, how about everyone with a project underway, sending a photograph and caption to Jack Cox, Editor of "Sport Aviation" (Box 229, Hales Corners, WI. 53130) for insertion in the "What Our Members are Building" section of the magazine. Also, "Sport Aviation" periodically prints a list of projects under construction. Send Jack your name and address and mention you are building a VariViggen. 150 builders on the next list would look real impressive!

- - - - - - - - -

I didn't really think anyone would build the landing gear first, but Mike Melville (S/N 115 did. Excellent work, Mike. He's done with the inboard wing and most of the control system and may be the first to fly!

PHOTOS OMITTED

CONSTRUCTION MANUAL. For sometime now we have been wanting to provide photographs of the construction details. Since we did not take these

during the construction of N27VV, we had been looking for a project on which to begin the photo series. Jim Cavis, S/N 031, has agreed to not only get professional quality detailed photos, but to write a construction manual with detailed information on tools, jigs, materials, construction hints, etc. This will be similar to the type of information on pages 11 and 12 of the plans but very detailed and expanded to about 30 pages, referring to approximately 75 detailed photographs. It will be published in two parts. Part one (fuselage, canard, inboard wing, vertical stabs, control system, and landing gear) should be ready by March or April and will include drawing changes to use the larger AN 220-2 control system pulleys which are much easier to obtain than those shown in the plans. Part two (outboard wings, canopy, engine installation, instruments, electrical system, seats, and fuel system) should be ready by about the end of the year. Price for the manual will be between $15 and $25. Complete details will be in the next newsletter. The following is a sample of photos from Jim's project taken in December. He now has the entire control system installed and is working on the landing gear.

VVN3, Page 2

ACTIVITY with N27VV has been almost nil for the last two months since we have had it in the shop to develop tooling for the fiberglass parts and exhaust system. Before N27VV was hangared though, Edwards Air Force Base invited us to participate in their open house display last November. The VariViggen blended in well with its red, white and blue, and fighter appearance. Also, writers Bill Cox, Don Dwiggens, and Peter Garrison did flight evaluations of the VariViggen that month. Keep watching for articles in "Flying", "Plane & Pilot", and "Science and Mechanics."

We are planning to have N27VV flying in time to take it to San Jose, where we are guest speaker at EAA chapter 62 banquet meeting on February 15. We have been giving several presentations to EAA chapters and other interested groups. Then we will be filming a movie sequence for a film which depicts the 1990's. The VariViggen strafes and bombs a futuristic-looking car in a desert canyon area, then crashes - the crash is done with a model, of course!

The airplane will then be inactive again for some improvements (see special performance), then we plan a U.S.A. tour with many stops, including of course, Oshkosh '75. We'll have more information on where and when in a future newsletter.

VariViggen plans have received NASAD approval in AA category.

COMPONENTS. We are behind the schedule we made in October for supplying the machined parts and fiberglass parts. What we thought we could do in a month has taken two or three (kinda like building an airplane!). the good news is that the machined parts for the first 25 airplanes are complete and they are beautiful. All steel parts are cat plated and baked. The nosegear strut is hard chromed and precision ground. Some builders have found it difficult locating the O-rings, backup rings, and scraper for the nose strut, so we have stocked up on these and can supply them with the nosegear housings. We also plan to build the NG36 scissors and NG20 'Y' bracket in machined aluminum with bushings to replace the welded homebuilt. Thus, we will be supplying the complete nosegear with the Scott assembly. We plan to offer this complete nosegear to builders of other aircraft types, but only after VariViggen builders have been supplied. Availability is now for the machined parts shown as "immed" in the catalog for the first 25 sets. The second production run will be available in one to three months.

The fiberglass parts will all be made in first-class tools being prepared by Fred Jiran, well known in the sailplane crowd for his excellent work with European, glass sailplanes. All tooling was redone from my prototype molds at considerable expense, but the result will be much higher quality parts without the waviness seen in N27VV's parts. All parts will be supplied in primer gell coat finish. The visor part (F27) has been modified, raising by one inch the portion which connects to the leading edge of the windshield. This results in a better looking, further-aft slanted windshield, more instrument panel space, and a smoother matched mold line to the nosecone. If you have not already cut out the top edge of F41, leave it about 1 1/2 inch taller than on the plans and trim to fit F27. If it is already cut, it is a simple task to scarf on an extension. F20 can be notched down between the longerons to provide clearance for long radios or instruments to extend out over on top of the canard aft spar. Notching F20 all the way to flush with the canard top will not weaken the structure. While the external fit should not pose a problem, it is suggested that you trial fit F27 before skinning the fuselage sides so any builder tolerances can be trimmed out.

The cowling tooling was a considerably larger task than we had anticipated due to the changed mold lines to enclosed the new exhaust system. In the design of the new cowling we made two decisions that will reduce the cost of your aircraft by over $200. First we are not using a prop extension. I originally thought this would be justified to provide a better looking aft closure. However, after finding that the prop extension now costs over $100, we modified the cooling outlet to provide a well-streamlined aft mold line without moving the prop aft as shown on the plans. Also, we are not using an expensive aircraft exhaust system. Instead of an expensive aircraft muffler, we used a simple manifold terminating in the center under the prop with the multiple hole outlet. The entire system was made up from stock bends (available at Midas) at a materials cost of less than $12. It's quiet and located so no exhaust-prop impingement occurs. The cowling is less bulky than it would be with a standard aircraft exhaust system and, best of all, you don't have to but the exhaust system - have you priced them lately? Full details and pictures will be supplied after all tests are completed.

We could produce cowlings by February 15, but we will not start production until all flight tests on the prototype cowling are completed, thus we expect cowling availability toe in mad to late

March. F23, F28, and F27 will be available by March 1. We only plan one master tool per part so all fiberglass parts can be made at a rate of only one set per day.

The following items are still planned, but we cannot schedule their production until we have a better idea of the demand and can afford the investment in tooling: V-MG19, V-MGMA, V-RMA, V-MG14, VVSC, Engine Mount, Fuel Tank, Exhaust System.

The car-top "wind tunnel" manual availability has been delayed until this summer. We built the new prototype system (see photos) but experienced failures with one type of the potentiometers used, after about five hours testing. A redesign is required, plus the demands on our time are preventing us from completing the textbook at this time. We were quite pleased with the new "wind tunnel" system as it gave us very accurate data in developing the aircraft shown in the photographs, which is a design we are building in order to break the existing world records for distance and speed in the under 500kg weight class.

We are also delaying the Owners Manual, for a different reason, though. FAA is now proposing that homebuilts fall under a new set of regulations for custom built aircraft in which a builder can do his own annual inspections and maintenance if he has a "repairman's certificate," given only to the builder. If you buy your completed homebuilt from someone, you would have to have maintenance done by an A& P mechanic. Also required is a manual. There are several different proposals for the manual format and contents. One by FAA, one by EAA, and still another by NASAD. As soon as it is decided what the regulation will specify, I will arrange the VariViggen Owners Manual to match, including all additional information specified in our catalog, of course. If FAA still has no regs by this summer, we'll publish it anyway, since it has alot of important information for VariViggen operation.

PHOTOGRAPHS OMITTED

SPECIAL PERFORMANCE WING. We have started construction on an entirely new outboard wing panel design for testing on N27VV. First, a little background: We have done extensive testing on a new construction method using urethane foam and hand layup unidirectional fiberglass. I do not mean the Rand formulae of wood construction with foam and Dynel surface development. We actually make a tapered spar very easily by laying up layers of unidirectional glass, carve a wing using only three rib/templates, and cover with two crossed layers of thin unidirectional cloth. this method is light, strong, requires no particular skills or tools, and best of all, can be done in about 1/4 of the man hours required to build the metal wing. If this system meets test expectations, we will supply plans for outboard wings and rudders, thus taking the aluminum construction totally out of the design. A small cost savings is also possible. Since the unidirectional glass with the epoxy surface treatment is somewhat difficult to obtain in partial rolls, we are importing a large quantity from Europe and will make available kits for the outboard wings and rudders. No aircraft-quality wood is required.

Now, for the really big news - the aerodynamic design of the wing panel. The original panel is a very, very conservative design from the stall standpoint, and retains the flat bottom out to the tip for ease

of metal construction. Now that I have actual flight test data, I can design out some of the unnecessary stall margin, and reflex and twist the wing for optimum performance. I wouldn't recommend this for a new design, but it can be done with low risk, using actual flight test data. Considering the trip requirements, and designing for best climb and cruise performance without excessively reducing the G-capability, I have arrived at the following design and have started construction:

	Original VariViggen	VariViggen SP	Increase
Span ft	19	23.7	25%
Area sq ft	119	125	5%
Aspect Ratio	3.03	4.47	47% !
Span Loading	89.5	71.83	-20%

SKETCHES AND GRAPHS OMITTED

Conservatively, we estimate a 25% increase in rate-of-climb at gross weight and a five to seven mph increase in cruise speed. That's almost 180 hp performance on the 150 hp engine! As you can see from the sketch, the new wing has a 15 gallon aux. fuel capacity. It will fit the inboard wing built to your plans and uses the save V-WAA (WA2 and WA3) wing atch. assembly as is used on the original outboard wing. It will also tie in directly with the current design AB10 aileron pushrod and should require no other changes.

In addition, we are going to incorporate the recent NASA-developed "winglets" developed by Dr. Whitcomb in an attempt to further increase rate-of-climb. In summary, if the SP works as I think it will and retains the stall safety, we will have a very competitive performance aircraft to go along with our already superior handling characteristics. But that's an if, so please don't bother us alot with further questions now; we should have test data and a decision whether to make plans available by Newsletter #4. I do suggest that you hold off on purchasing materials and building the outboard wing if you have not already done so.

OTHER Modifications - True, the VariViggen is not a 4-place airplane, but it can easily be made into a 2 + 2 configuration with plenty of room and visibility for a 140-lb wife and one or two children, combined weight up to 110 lb. The sketch is self-explanatory. This is the best way to add some family utility without compromising cruise performance. Scaling up the outside dimensions to add more people will result in either slower speeds or higher fuel flow, depending on engine selection.

SKETCH OMITTED

As a two-place, the rear seat area is much larger than is usually needed, and a relatively minor modification can be made to increase fuel capacity, baggage capacity, and still hold a 6' 4" back seater in relative comfort. Again, the sketch is self-explanatory. This is probably the best way to increase range, since it does not add any complexity to the simple gravity-feed fuel system.

SKETCH OMITTED

ADHESIVES. I am still hearing about some builders using obsolete wood adhesives and varnish. That was S O P years ago, but inexcusable now that modern epoxies are available. With modern epoxies, the wood structure should last indefinitely. Here are two more very good adhesives: 1. FPL glue 16-A, available from Aircraft Spruce, Bx 424, Fullerton, CA. 92632, at $11/qt or $29.90/gal; 2. West System Epoxy, available from Gougeon Brothers, Bay city, MI. at $19.95/gal plus $5 for hardner (specify 206 hardner for 40 minute pot life). This latter one sounds excellent as it has a relatively fast cure of six hours and can be used as low as 40 degrees F temperature. It's a 5 to 1 mix, has a relatively low viscosity, and can be used directly for painting structure. It provides a 100% molecular bond between coats without surface preparation. For gaps over 1/32", it can be thickened with "401 fibers" (1.90 for a bag - enough for the entire aircraft) to fill even large gaps without
decreasing strength. Send Gougeon Brothers an extra $ for their manual on this epoxy system. Pastor Jenkins, S/N 177, is using it on his VariViggen. He completed his fuselage structure and canard in only 12 days!

PLANS Changes - Be sure to incorporate these revisions into your plans Now.

Location - PL - Plans
TR - Tech Report
NL - Previous Newsletters

Category - MEO - Minor error or omission
OPT - Optional improvement
DES - Desirous change - Does not effect flight safety but should be incorporated to improve aircraft or correct a fault
MAN - Mandatory change - Must be incorporated as safety of flight is affected

Category	Location	
MEO	NL2 pg 2	Change phone # to 824-2645.
MEO	PL pg 11	Center of page, change "W.L.18" to "W.L.22".
MEO	PL pg 4	Furane Plastics has closed their N.J. office.
MEO	PL pg 4	Western Ply & Door Co. no longer uses "Western" in their name.
MEO	NL2 pg 3	Wrong address for Spencer. Use the one on plans pg5, 8410 Dallas, Seattle, WA. 98018.
MEO	PL pg 50	Newsletter #2 changed the 1.63 and 1.7 dimensions to 1.75 because we found some belcrank bearings (MG7 - MS20218-2) with an outside flange of 1.75. Since then I purchased some MS20218-2's from Arts Surplus (address on plans pg 5) for $.75 each, that have a flange diameter of 1.67 which is the correct O.D. shown in the mil spec. We are machining the RAF-supplied MG5 & MG4 parts to fit the 1.67" bearings. If you are building

		your own MG5 & MG4, I suggest you get the MG7 bearing first, and fit the inside diameter to a slip fit on the bearing with a chamfer to clear the bearing radius. The RAF-supplied parts accomplish this.
MEO	PL pg 18,38	Some of you have found interference of the SA1 stick torque tube with F63 bulkhead. F63 should be modified in the center to have a notch rather than a hole to allow the tube to fit higher. If F63 is already fabricated, cut out the top edge and install a doubler plate as shown in the sketch. Also, to provide more clearance, you can move the entire stick assembly down by increasing the .8 dimension on SA12 & SA13 to 1.0 inch (plans pg 38). **SKETCH OMITTED**
MEO	PL pg 25	SPAR G - 2.3" dimension should be 2.5" so spar comes flush with the capstrips that cover rib WR25. This taper on spar G can be trimmed after installation to fit flush with the capstrips.
MEO	PL pg 38	Tube sizes on Detail A are incorrect, change to 3/8 x .063 spacer clamped by bolt & 1/2 x .063 spacer welded to SA2.
MEO	PL pg 42	RB2 - the 1/4" hole callout is wrong - should be drilled to be riveted to belcrank bearing the same as AB4, pg 40. A 7/8" hole & rivet pattern to fit RB5 is required.
MEO	PL pg 5	Cotterpin AN 330-3-3 should be AN 380-3-3.
MEO	PL pg 42	Cleveland Tool Co. no longer makes ball screw actuators. The correct part is RO 308, ask for 1/2 ft of screw and the RO 308 ball-nut assembly (about $45!) from Los Angeles Rubber Co., 2915 E. Wash., L.A., CA.
MEO	PL pg 25	Cut holes in WS24 outboard end for the landing gear cables before glueing in. (Notch in about 1" where it butts to WS7).
MEO	PL pg 53	Diode number omitted. Can be # 2761135 from Radio Shack. Also RG58/U can also be RG58/C or RG58/AU.
MEO	PL	2024 T-3 & 2024 T-4 aluminum callouts are reversed in several places in the plans. These are interchangeable in all cases.
MEO	PL pg 11	First column, change "quarter square" to "triangle".
MEO	PL pg 13	Antennae rods are 14.15" long. Don't scale dimension from drawing.
MEO	PL pg 18	F63 outside edge is drawn at B.L. = 12.25. This should be B.L. = 12.4. If you have already cut out F63, just ship out about 1/8" wider with 1/8" ply strips.
DES	PL pg 45	The forward bolt passing through NG37 cannot be tightened down hard without binding NG20 & NG36. While this has presented no problems on N27VV, it is a poor design practice & I am improving it by providing a spacer for the bolt to tighten on. The spacer can be 5/16"

x .035 steel tube drilled out to press onto the 1/4" bolt. Drill out NG36 to 5/16" to fit over the spacer. I also strongly suggest a short length of 3/8" tube welded in the arms of the NG20 "Y" bracket to provide a better bearing surface. Also note that NG36 center pivot must be offset to prevent interference when the strut is deflected. Thanks, Mike Melville, S/N 115, for these suggestions.
SKETCHS OMITTED

VVN3, Page 6

BUILDING Hints - Most of these were suggested by builders. If you have suggestions, please get them in for Newsletter #4.

Build the fuselage and/or inboard wing jig at W.L. = -3 instead of W.L. = 0 to facilitate installation and removal of parts without having to notch the jig.

F10 can be bent in place if done in the order stated on pg 11, but it takes alot of clamps since it is relatively stiff. you can saw notches in F10 about 1/2 way through, every 2 inches from F.S.22 to F.S.48 to make it easier to bend. The strength along F10 is not needed. Its primary function is to tie F11 and F15 together.

When permanently installing Spar E, glue in WS2, WS5, WS6, WS7 and WS9. Let dry. Then bend WS1 over to fit and glue in WS1, WS8, WS10, WS3, and WS4. This keeps the bend in WS1 from deforming the flat bottom.

Urethane foam (2 lb/cu ft) can be substituted for the balsa everywhere. Cover with one layer of 9 oz fiberglass - go easy on the resin, it's heavy.

PE2, pg 39, can be fabricated easier in two parts and overlapped in the center thus: **SKETCH OMITTED**

The nutplates for PE2, pg 39, are hard to get at, after installing WS3. Install them on F152 before installing the wing spar.

F5 is cut curved, not bent.

90 degree or 45 degree plywood is okay. I used 90 degree throughout.

A good stapler for skinning is the Aero T50. Use 3/8" long staples. I took a large screwdriver and ground a scoop shape on the blade to use as a scoop to pry the staples out once the glue is set.

Due to their slant, bulkheads F41, F70, F91, and F121 come out short when the waterline drawings on pg 17, 18, and 19 are used as patterns. Some builders have made them short and just adjusted in place by notching up the longeron slots and shimming the top. This is perfectly fine, but if you haven't cut yours out, here are the dimensions for bulkhead patterns which should fit quite well.

SKETCHES OMITTED

Tom Hendricksen, who is building S/N 169 with a "full" IFR instrument panel, sent in his panel layout and a modification to mount the panel further aft, to provide clearance for the longer radios. Note that F27 visor does not quite extend to cover this panel but a small extension could be added.

SKETCHES OMITTED

SHOPPING

Stolp Aircraft, 4301 Twining, Riverside, CA 92509 has 2024 alum extrusion angles.

Columbia Airmotive, Box 436, Trout Dale, OR 97060, (503) 665-4896, has good prices and stock on hardware and has the 500-5 wheels and brakes for about $115.

G & J Aircraft, 1115 So. Sultana, Ontario, CA 91761 (986-6534) has good hardware stock and good "scrounging" prices.

Wicks Organ Co, Highland, IL 62249 will supply spars cut to size and has a complete plywood stock.

J & M Aircraft supply, 1014 Joseph St., Box 7586, Shreveport, LA 71107 has a good overall hardware and materials catalog - send for it.

Plywood & Door Co., 1555 Santa Fe, Long Beach, CA has birch 1/4" plywood 5-ply with outdoor glue for only about $.35 per sq. feet! This is not aircraft ply because it has some patched imperfections, but is still excellent quality and perfectly adequate. They also have a complete line of all plywood sizes, aircraft and non-aircraft - write for list, or go see them if you can. They deal only in plywood and service is good.

Wiebe Wood Products (Newsletter #1) price per quart of M666 Epoxy glue is now $8.50 plus postage. Mr. Wiebe tells us that the price will probably be going up again, but that he will continue to supply our builders as best he can and will keep the price as low as possible.

FLIGHT Test Assistance - We are planning to provide a pre-first flight inspection and initial flight test assistance service for our builders. This would involve us visiting your flight test area, giving your aircraft a very complete inspection, and rigging check, prior to first flight and either flying your first flight or checking you out in N27VV to improve your proficiency for your first flight. Providing flight test assistance in expanding the flight envelope of your airplane would also be very beneficial in assuring flight safety. This service will only be provided to those who are building the airplane without major modifications from the plans, and flight envelope expansion on your aircraft will be limited to the envelope shown in the aircraft operating limitations, plans page 3.

We will provide this service to the first three builders who complete their aircraft, free of charge except for transportation costs. Transportation costs may also be eliminated if we can work it to coincide with another trip.

Clarification of placement of WR12.6 with respect to fuselage. It's probably best to install WR12.6 capstrip after skinning fuselage sides. Fuselage skin should extend about 1/4" to 1/2" below wing top. Fuselage skin is notched to fit over wing spars. **SKETCH OMITTED**

BARTER Corner - Everyone is welcome to a free ad for this section, after all, it's your newsletter.

Jim Cavis reports he can sell the Pointer portable model 3000 ELT with voice modulation for $96.00 FOB Phoenix. That model lists for $160.00. Contact him directly at 8344 E Turney Ave., Scottsdale, AZ. 85251.

Charles Allen would like to trade a set of new Cleveland 600x6 wheels and brakes for 500x5, or will sell for $75.00. He's also looking for an O-320 and the Scott nose wheel. Write to him at 1022 Hoedel Ct., Lafayette, CA. 94549.

Jim Brunson, 5225 W. Ave. L-2, Lancaster, CA. 93537 has an O-320 Lycoming for sale.

Ken Winter, 1538 E. 66th., Tulsa, OK 74136, S/N 133, has a partially completed BD-5A for sale.

VARIVIGGEN NEWS NO. 4 APRIL 75

Published quarterly by Rutan Aircraft Factory
Burt & Carolyn Rutan
Building # 13, Mojave Airport
P.O. Box 656, Mojave, Ca. 93501
(805) 824-2645

Subscription rate: $4.75/yr, back issues/$1.00 each
Current issue is included with Technical Report purchase.

N27VV has seen a lot of action since newsletter number 3. We've logged nearly 100 hours on the new cowling, including trips to San Jose, Watsonville, and Flabob, Ca.; Phoenix, Az.; and Las Vegas, Nv. In addition, I flew the action-packed chase and bomb scenes for the movie "Death Race 2000," which opened April 30 in theaters in the Los Angeles area. We had a lot of fun doing the film, which required many hours of flying, doing close-in passes on race cars. On many of the passes, explosions were set off around the car just as I pulled up. The model used for the crash scene was built from our R/C model plans. The movie is rated R, so be ready for a little crude language and nudity.

A lot of our recent flying has been to give rides and to put time on the new cowling. The cowling has added more performance than I thought it would and cools the engine much cooler than the old configuration. I'm now cruising at 152 mph at 75% power at 7500 feet with the external fuel tank, which means 155 without the tank. When we fly the new SP wing we expect to cruise close to 160 on the 150 hp Lycoming.

The VariViggen was featured in May issues of "Flying," "Private Pilot," and "Plane and Pilot" magazines. As for our comments on the articles, I think they were well done with a few exceptions: The VariViggen does not lose altitude during a power application at normal approach speed and is not control limited as John Olcott mentioned in "Flying" (a retraction has been sent), and Don Crane did not make a full aft stick circuit and landing (that's not hardly recommended for a checkout!). Watch for another article in a future issue of "Mechanics Illustrated."

Scheduled dates coming up include presentations at EAA chapter 40's meeting at Van Nuys, Ca., June 13, and the AIAA/EAA symposium at Boeing Field in Seattle, Wa., June 28. We'll also be attending the Porterville (Ca.) flying, June 16, and Oshkosh flying, July 29 to Aug. 4. Ken Ashdown (SN 069) from Ontario, Canada, will be giving a technical presentation on the VariViggen at the First Canadian Symposium on Recreational Aircraft, Ottawa, Carleton University, June 23-25.

Another article about N27VV was written in the "Hangar Flyer" publication by Don Pridham, editor of EAA chapter 92, Orange County, Ca. His comments are reprinted here:

"When we arrived at Flabob, the wind was still calm, but that nice state of affairs didn't last long enough. A REALLY strong 90 degree Santa Ana wind came up for quite awhile there, and everyone walked out near the runway to watch the sheep and goats being separated... At

about the height of the wind gusts, Burt Rutan and the VariViggen came zapping into the pattern, came down like he was riding a string, painted it onto the runway without a trace of strain, pain, crabbing, slipping, or anything, turned off in about 6 lengths from touch-down, and taxied effortlessly past toward the tiedown. In the back seat was his enthusiastic and charming wife, Carolyn, and BOTH of their girls!

I kinda remember seeing and talking to a large number of you friendly folks up there, looking at bunches of fine craftsmanship, and eating some excellent food prepared by Chapter 1, but what happened next sort of erased my mind totally on most other happenings. Joel Confair and I finally found Burt Rutan, who had been very busy fielding the myriad questions about the VariViggen. Joel had wanted to verify the time and place for our next meeting with him. Out of the blue, Burt says, "Don, how'd you like to take a ride in the VariViggen?" My jaw drops. Joel's drops further. "When?" "How about right now", he says. My mind is already popping circuit breakers as I'm thinking what Joel is mumbling (something about who's the Pres.) I consider of course stepping back, bowing a bit, and offering to let Joel go instead ---- HOWEVER, I have to live closely with a person who would never stop kicking my butt if I didn't go. ---ME! (So now I finally know -- when it gets down to me or somebody else for the goodies, it'll be me every time. Hah, the old id is really there, just like the shrinks say it is!)

So in a numb hazy smiling kaleidoscope we belted in, taxied out staring at a few hundred camera lenses, and made an unreal take off. I watched the elevators very scientifically, and he brought them way down to lift the nose up. It came up very quickly and instantly we were going up at a shocking angle and rate of climb. The minute we were off, he started making a series of 90 degrees right and left turns. After a pass of the field, Burt announced he would demonstrate "departure stalls" (one can hear conversation very well, even though tandem). Thereupon he hauled up the nose in a steep left climbing turn, held it awhile, then stated, "OK, there it is." He then executed beautiful right and left steep banks and directional changes, all the while when it was technically "stalled". Actually we were still seeming to climb about 500fpm and things never felt the least bit "loose".

Burt cranked into the downwind, aiming approximately at the cross on mount Rubidoux, approached the cross, CAME RIGHT UP TO THE CROSS ABOUT ONE INCH AWAY, and casually flicked into an instant left bank like a bored housefly in July. If I'd tried that in my Mooney, crews would have been picking up pieces scattered a mile East of the mountain, and I'd have been crucified. It's really strange though. I have a very healthy respect for flight, and what a plane can and can't (or shouldn't) do, yet not ONCE was I ever the least bit anxious, uneasy, or apprehensive. The VariViggen has a solid feel of confidence and safety throughout the entire flight regime. It is really the finest maneuvering craft I've ever had the pleasure to ride in, and at all times you REALLY KNOW IT'S FLYING. Landing was so apparently simple as to be nearly anti-climactic. Burt had saved another few surprises for the ground, though. Naturally, he had landed super-short, and said, "OK, watch this. We'll go taxiing right between those parked birds.", pointing to a pair of high wingers moored practically tip to tip, with ropes coming down at 45 degree angles and meeting about 6 feet apart. "Have you really thought seriously and adequately about this

decision?", I say, as he goes chugging merrily through like he was only pushing a wheelbarrow. I sweat a bit finally that time, as I pictured three airplanes suddenly hugging each other in a big MUNCH! The ground handling is fantastic, as it can, I believe, turn in its own length and width, or bring its nose up touching a building, then turn left or right and taxi away without bumping a wing. (No reverse needed). People -- things are happening in EAA. Thanks, Burt."

VVN4, Page 1

CONSTRUCTION MANUAL - Part one of the photo-illustrated construction manual, written by Jim Cavis, SN 31, with approximately 100 photos, is just about completed (includes fuselage, canard, inboard wing, vertical stabs, control system, and landing gear). Part one also includes helpful sketches on jigs and numerous building tips. The written information is similar to plans chapter 5, except expanded to about 35 pages. Also included are pulley bracket drawings for using of the AN220-2 pulleys. Part one will be ready June 15th. Cost is $18.50 (first class mail) and $20.50 for Overseas (Airmail).

SPECIAL PERFORMANCE WING - The SP wing configuration still looks very similar to that shown in newsletter number 3, but I've greatly simplified the construction method and upped the wing fuel capacity to nine gallons per wing. The construction method was verified on the fiberglass VariEze wing, which was built in two days. We have completed all necessary structural static tests, thermal tests, and fuel compatibility tests. I'm now awaiting another shipment of unidirectional fiberglass to build the flight item SP wings and hope to have sufficient flight test data by mid June to show the acceptability of the new wing.

ADHESIVES - Gougeon Brothers, 706 Martin St., Bay City, Mi 48706, whom we mentioned in newsletter number 3 as having an excellent epoxy glue for wood (105 Resin plus 206 Hardener at $25/gallon), now has a mini pump system which attaches to the cans and dispenses the correct ratio (5 to 1). Each stroke of the resin pump gives 1 oz.; each stroke of the hardener pump gives 1/5 oz. Good news is the price: $3.50 for both pumps. Get two sets; they're plastic and may have a limited life. Gougeon 105/206 still looks like the best resin, although Aerobond 2178 is also excellent (available from Aircraft Materials, 850 E. San Carlos Ave., San Carlos, Ca 94070).

BUILDER'S PROJECT REPORTS - The following reports/photos were sent in by builders and I agree with the building hints suggested. You might consider them for your project.

Charles Allen (SN 47) on fuel tank -"The tank was made this way mainly because I had on hand a sheet of 6061 .050 alum., which is a weldable alloy, but of course harder and springier than 5052 - I drew up the two end bulkheads on paper using rounded bends but straight sections in between - Cut the two body pieces at least 1" longer than needed, then bent the "rounded" corners on a friend's sheet metal brake. A series of slight bends is all that is needed, frequently holding the piece over the full-size end patterns to check accurate progress. A right angle flange is bent where the top and bottom pieces join. The two pieces are then joined by about 3 clecoes on each side on the inside

flanges. Then the exact cut-off line on each end are drawn on the tank - and the tank is trimmed - I used a table saw, a plywood blade, and a lot of cotton in my ears. And of course safety glasses at all times! Each tank end is then set on the alum. sheet to be used for the end piece and traced. The ends are cut out allowing at least 1/2 - 3/4" for a bent flange all around. Saw cuts are made into the corner areas. The good thing about this is a form block for each end is not necessary - Just a 2x4, or 6, clamped along the straight sections and those sections bent over. The small tabs are bent over a small block. The ends are clecoed onto the tank body. First the .032 baffle is made, put in place. Also the holes for the filler neck, tank gauge and vents and bottom fittings are drilled - I do not flange those holes - Welding the fittings directly to the tank is adequate. The whole thing is then taken to a good heli-arc welder - I left the tank gauge hole open - checked for leaks and then used sloshing compound on the inside to make sure - The tank gauge was bolted to .063 alum. plate which was then riveted to the top of the tank using closed-end pop rivets - Sealing compound was put on between tank and plate first - Tank was then primed with zinc chromate and painted - Sounds complicated - but it really is not." **SKETCH OMITTED**

Vernon Williams (SN 189) on reflex screw (RM5/RM6) - "The reflex screw is from a 5" craftsman "C" clamp. It is a 5/8 - 8 acme thread. I cut the neck off the clamp and turned it to fit inside a 3/4" tube. The whole tube assembly is brazed onto the gear of the motor (Ford unit) which has been turned down to fit inside the tube... When turning the drive gear down on one of these motors some precautions are needed because the teeth of the drive gears are hardened and will eat a common tool bit right up. First grind the teeth down to near the base diameter of the gear. Then, you can chuck the drive gear directly in a three jaw chuck and by using a fast turning speed and carbide cutter you can turn the rest of the gear down."

Vernon Williams on inboard wing spar - "The key to this method of construction is to build spar E first. I built mine complete out to FS 25. In building the spar, make your wing ribs first and take the measurements for the spar height from your actual ribs and not from the plans. This is necessary because the drawing shows the height at FS 153 which is in the middle of the spar. Also at least one of the dimensions given is off at least 1/2"* ... I made a stub (about 12") WR25 to use as a spacer and have made the WS9 and WS10 webs. I plan to drill all the holes to mount the wing attach fittings, main gear pulley, and the aft gear pivot point before I even mount the spar on the firewall. The main advantage I see is that when you mount the spar on the firewall (be sure and support it or the weight will pull the firewall down) it gives a nice straight, level, and strong datum to build the wing from. Also, the spar can be out where you can drill the important holes in a drill press. In assembling the whole mess, the WR25 can be slid in and turned up to fit in place and the WS9 and WS10 webs can then be glued in place (the wing attach fittings can be used as clamps) and then the rest of the ribs can be added ... Instead of trying to bend WS1, I made it straight and then bent the WS3 and WS4 caps to form the curve of the spar. Then I set my bandsaw to cut the 4 degrees bevel and trimmed the height slightly oversize. Then I got out my trusty Jack Plane and planed it to size. This makes a nice looking spar which should (I hope) make building the wing easier." * Be sure

to note the correction on the spar height at B.L.=0 (7.8 dimension should be 7.3).

PLAN'S CHANGES - Be sure to incorporate these revisions into your plans now.

Location	PL	Plans
	TR	Tech Report
	NL	Previous Newsletters
	CAT	Catalog
Category	MEO	Minor error or omission
	OPT	Optional improvement
	DES	Desirous change - Does not effect flight safety but should be incorporated to improve aircraft or correct a fault
	MAN	Mandatory change - Must be incorporated as safety of flight is affected

CATEGORY	LOCATION	CHANGE
DES	PL pg 59	NG38, change 1/16 to 3/32 cable.
OPT	PL pg 40	AB4, move cable shackles 1/2" closer to pivot (change 5.5 to 5.0) to allow sufficient cable clearance with MG6.
MEO	NL#3 pg 7	Change Aero T50 to Arrow T50.
MEO	PL pg 51	MG42, spool 0.5" width should be 5/8" to

		allow sufficient cable room. Change 1/16" roll pin to 3/32".
MEO	PL pg 24	7.8" dimension on Spar E should be 7.3".
OPT	PL pg 39	Tilt the lower edge of PB2 rearward about 1/2" to allow more cable clearance with SA6.
MEO	PL pg 46	NG1, .5" should be .6". .85" should be .95".
DES	PL pg 38	SA5 has inadequate lateral stiffness. Stiffen by welding 3 pieces to top rim as shown: **SKETCH OMITTED**
DES	PL pg 44	Engine position is shown on the plans only by locations of the mount pads on the engine mount drawing. To obtain more prop clearance and the correct fit to the cowling, the crankshaft at the prop flange should be located at W.L.32 (prop flange at F.S.186.5). For conical mounts (not dynafocal) the top mounts should be at W.L.36.2 and the bottom mounts at W.L.26.55. More details on this are shown on the instructions included with cowlings. Delete the F.S.189 circle on PL pg 6. Add a 12" circle with center at W.L. 32. Lable it F.S.186.5.
OPT	PL pg 39	PE2, change 1.3 to 2.0 and change 1.8 to 2.5. This moves cable forward to provide extra clearance with MG43 gears. (May not be required - depends on your MG43 installation.
MEO	PL pg 28	VS1, 2.8 dim. should be 2.5.
MEO	PL pg 17	A fairlead should be installed at B.L.4.3 and W.L.6.3 on F51 to position the rudder cable below F21.
MEO	PL pg 45	Turnbuckle required on 1/16" cable that runs gear up & down cannot be a standard turnbuckle since they use up too much cable room and would run up on either pulley. Total disturbed cable length must be less than 4 1/2" including nicropress sleeves. N27VV has a short homemade turnbuckle made from 2 shackles and a short length of threaded alum tubing. Another method is to eliminate the turnbuckle and adjust tension with a small idler pulley. Vernon Williams substituted a chain as suggested on the plans and he reports excellent results with a Boston K2512 pulley and No. 25 chain.

LANDING GEAR RETRACTION GEARING

We are recommending mandatory changes to increase the retraction/ extension forces on the landing gear . These new gearing changes will allow use of either the Dodge or Ford window motors and will result in positive gear retraction for all allowable aerodynamic conditions . NOSEGEAR - The system shown on the plans is inadequate for inflight retraction loads with the nosegear door installed, particularly when using the Ford window motor. It is necessary to gear the motor similar

to the maingear motor installation to provide adequate retraction torque. Ratio required is between 3:1 and 5:1. The following gears, available from Boston gears (check your local Yellow Pages), will work well:

Boston No.	P. Dia	Hole	Price (1971 Catalog)	
NA11B	0.6	5/16	$1.95	Mount to motor
NA50	2.5	3.8	$7.50	Mount on NG6

Be sure to test the power of your retraction by pulling 15 lb aft at the nosewheel with a fish scale while the gear is being retracted. The following quote and photo from Mike Melville further clarifies the installation:

"I am delighted to report that my nose gear retracts effortlessly in about 10 seconds even with a constant 15 lb aft pull. Pulling the pin and swinging the gearmotor away from the gear allows the nosegear to freefall down and lock. It works perfectly and I could not be more pleased. Also, when I lowered the gear ratio, I did not move the spool NG1, but I lowered the gear motor downward until the small gear engaged the bottom of the large gear. This worked out well, as nothing now protrudes up into the canard."

I understand it is possible to find a gear which will mesh directly with the gear provided on the Ford or Dodge unit. This eliminates the need to adapt a small gear to the motor. Don't ask where to find this gear though, as I have no source and those who have found one scrounged them at surplus outlets.

MAIN GEAR - Plans call out a 1:4 reduction for MG43 gears. This should be increased to between 1:6 and 1:9. The following Boston gears will fit and work well, providing a 7.3 ratio:

Boston No.	P. Dia	Hole	1971 Price	
NA11B	0.6	5/16	$1.95	Mount to motor
NA80	4.0	1/2	$9.40	Mount on MG41

NB series gears can be substituted for the NA series on either nose or main gears. The following quote and photo further clarifies Mike Melville's excellent installation: (Photo on page 3)

"The view of the motor assy shows it temporarily clamped in position with 2 "C" clamps. I used a 12-tooth gear on the motor and 97-tooth gear on MG41. It retracts in 12 seconds and is not affected at all by pulling 10 lb outward on each gear (during retraction). My wife says I am like a kid with a new toy!! I have not had the courage to drop the main gear all the way from the top (emergency extension system) as I am afraid it will break something! It is probable that my MG6's will snap solid into place (down lock) when I do let it freefall. I will try this after I get the bottom skin on."

As I remember, I waited to skin the bottom also, before testing the emergency freefall system. MG6 (MG5 Lugs) have always snapped into the locked position during emergency freefall testing. Depending on your

gear motor and gears selected, you may have to modify the shaft in the gear motor and provide a shaft bearing on the outside of the gear. The following sketch shows Mike Melville's modification: **SKETCH OMITTED**

Of course, if gears are available which would mesh directly with the gear on the Ford or Dodge motors and provide 4:1 ratio for nose gear and 8:1 ratio for main gear, the installation would be greatly simplified. If anyone knows of a source of these size gears, let RAF know and we will print it in a future newsletter.

MAIN GEAR DOWNLOCK ADJUSTMENT

The plans do not show any adjustment on the snubbing of the gear in the downlocked position. I have noticed a slight amount of freeplay in N27VV's right gear after 400 hours that is not serious enough to require attention but I am recommending that you include an adjustable wedge that can slide sideways to provide downlock snub adjustment. The MG4 beams sold by RAF were machined shorter than the plans due to an error, but these will now fit well when used with the downlock adjustment. If you are making your own MG4 beams, make them approximately 1/4" short on the end so they will fit with the downlock adjustment. To provide the best downlock geometry with the adjustment installed and the shorter MG4 beams, move the pivot for the MG5 lugs outward (toward the wing tips) about .15" to B.L.34.15. This move is not absolutely required, though, if you have already located the pivot at B.L.34, the downlock will function with a thicker wedge on the downlock adjustment, and the gear total motion to the extended position will be closer to 92 degrees than the 97 degrees shown on the plans and the main gear extended position will be inboard of the B.L.40 position shown in the plans and should result in more even tire wear than on N27VV (I now have to reverse the tires during the wear cycle since they wear more on the inboard side). The sketches show the geometry of the downlock adjustment and the new position of MG4 and MG5 in the locked condition. **SKETCHES OMITTED**

BUILDING TIPS

You don't need to weld the caps on NG13 with the nutplates riveted inside. You can drill two 5/8" holes on the front or back near the ends and install the nutplates, or a locknut, after welding.

The following are the Lycoming-listed dry weights for the engines recommended for VariViggens: 0-235-242 lb, 0-320-273 lb, I0320-292 lb, and 0-360-285 lb.

Vernon Williams has ordered a ground-adjustable wood prop from Bernhard Warnke, Box 50762, Tucson, Az. 85705. This appears to be a good way to have the safety and light weight of a wood prop and also have the flexibility of the adjustable feature. (See March 75, "Sport Aviation" for article.) We are presently working with Sensenich in the development of a wood prop for VariViggens that is similar to the wood props they developed about two years ago for the Thorp T-18 homebuilt. More details after flight testing when this one is available.

The Fafnir number for the 5/16" belcrank bearing is BC5W11.

The following sketch shows the position of the skin scarf joints on the fuselage and inboard wing of N27VV. 50"x50" birch plywood was used.

Grain was 'forward-aft' except for the large piece on the inboard wing which is parallel to the leading edge. **SKETCH OMITTED**

SHOPPING - The following companies have excellent spruce kits for the VariViggen. They include all spruce cut to the sizes shown on plans page 4. I can vouch for their excellent quality. Write them for prices and availability. Aircraft Spruce and Specialty, Box 424, Fullerton, Ca 92632; Aircraft Materials Co., 850 E. San Carlos Ave., San Carlos, Ca 94070.

Some builders have had problems locating the very important decimal steel tape measure, suggested in Newsletter #1. Bill Riddell (SN 50) reports that he has access to a large number of the 61-112 rulers and any builder can send him a check for $6.50 which includes postage and he will send a ruler. Bill Riddell, 4575 Shadesview Dr., Pensacola, Fl 32504.

Lloyd Toll, Box 303, Hazen, Ar 72064 does excellent alum welding and is equipped to build fuel tanks for VariViggens. He has a lot of fuel tank experience. Write him for quote.

The following company has a stock of aluminum at 1970 prices, 50cents/lb!: McGowan Company, Inc., 560 E. Maitland, Ontario, Ca.

NEW PRODUCTS FROM RAF

Add the following items to your RAF Catalog. Prices and availability as indicated.

V-CSP - We have a limited number (5 ship sets) of the LS-806 pulleys in stock now. These are the 2-bearing pulley used in the primary control system (10 places) and fit the brackets drawn in the plans. They are new and equal or better quality than the best AN220 pulley. Price is $3.75 each if picked up here. Add 25 cents for each pulley ordered to cover packaging and postal/UPS shipping charge if you want them shipped.

V-INRIBS - This is a package of birch plywood pieces with all the inboard wing ribs (except WR46) drawn on them (full size of course!). The homebuilder saws along the lines with a saber saw or band saw to fabricate the ribs (eliminates scaling up plans). A 2-inch overlap is drawn on the longer ribs for the homebuilder to scarf together. Price $78.00. Availability JUN 20. Add $5 for packaging if not picked up at RAF. Shipped freight collect.

V-BKHDS - This is a package of birch plywood pieces with F20, F32, F41, F51, F63, F70, F91, F103, F111, F121, F137, and F152 drawn on them. Eliminates scaling up the plans; builder cuts along lines to fabricate bulkheads. Price $169.00. Availability JUN 5. Add $5 for packaging if not picked up at RAF. Shipped freight collect. This package also includes WR46 inboard wing ribs. 3/8" ply is marine fir AA grade.

V-CMAN1 - VariViggen Construction Manual (part 1) - See description elsewhere in this newsletter. Availability, 15 June '75. Price $18.50 including first class mail, or $20.50 for air mail Overseas.

VARIVIGGEN COMPONENTS

All machined parts are in stock in adequate supply except V-WAA which we are down to two ship sets and it will be about six weeks until we get more. We can sell the eight tapered pins separately if you want to fabricate your own straps and buy the heat-treated, cad-plated taper pins. Note that they are tapered 3/4" per foot rather than the taper shown in the plans. Thus, a standard pipe taper reamer can be used to taper your straps (before heat treat of course!). Price for the eight pins alone is $37.00 including packaging.

Some builders have asked why NGSA is so expensive. The following is a list of the operations required to build it, which gives you an idea of why the cost is so high: Cut three 4130 steel tubes to length and face ends, machine plug to close tolerance for shrink fit in tube, shrink fit plug and tube, fabricate 'U'-shaped part which fits the Scott assembly, weld assembly of five parts (weld backs up the shrink fit to assure no leakage), heat treat, grind strut, hard chrome, re-grind strut, mask strut, cadplate lower end, bake assembly for surface embrittlement. I've had the entire nosegear assembly from the parts in the first 25 ship sets on N27VV for the last 50 flight hours and have had no problems at all with any of the parts.

Do not order backup rings for the nosegear installation. The strut is designed as a low pressure assembly and provides excellent sealing with the o-ring alone with no requirement for backup rings. We will still supply the O-ring set and scraper to complete the nosegear assembly. If you are building your own nosegear parts, machine the o-ring groove to fit the o-ring only and do not use backup rings.

Installation instructions are included with all RAF-supplied machined parts.

All fiberglass parts have been in stock since March 5th. Installation instructions included with all fiberglass parts include drawings detailing the installation of landing light, all doors, engine cooling baffling, engine induction system, exhaust system, cowling exhaust shields, carb-heat system cabin heat system. Note that unlike conventional baffling, VariViggen cowling installation results in the magnetos and fuel pump running in cold air rather than air heated by the engine cylinders. This extends magneto life and eliminates vapor lock.

Instead of my description of fiberglass parts, I'm including a quote from a letter from Mike Melville (SN 115).

"What can I say, Wow! Much to my delight, my fiberglass parts arrived today, in perfect condition and beautifully packed. The shipping charge was very reasonable and the quality of the parts is outa-sight!! I could not be more pleased. I expected them to be good, but this is really professional quality. Just super! I also received my "Flying" magazine and was pleased to see the article about the Viggen. I think it is an excellent article and the photos are great. The new cowling

looks good in the last photo. I love mine, the finish is unbelievable. The instructions are worth their weight in gold as well."

The new nosecone design eliminates the F26 metal ring by providing a joggle which allows bonding the plexiglass dome on flush without a ridge on the outside.

Our packaging cost for the set of all fiberglass parts is $20.00. If you pick up these parts here at the Mojave Airport you can save $20.00.

VARIEZE

The VariEze, a prototype aircraft built at RAF since Newsletter #3, is nearing completion. First flight should be before June 1st. This aircraft is being built as a research project to evaluate the feasibility of a high-aspect ratio (eleven, on wing and canard) canard configuration for optimum cruise performance. This aircraft may be offered in plans and kit form if it proves to have good flying qualities and safety and when we have completed all flight tests, including spin, flutter, environmental, and reliability tests. In the mean time, we hope to use it to capture most of the important speed and distance records in the under 500 kg weight class. Releasable specs are shown in the following. Please don't ask us for any more information than is shown here as all other information must be withheld pending completion of the appropriate development and testing. When it's available, further information will be in "Sport Aviation" magazine and in "VariViggen News."

Construction - Fiberglass/Foam composite, no structural wood or metal
Wing Area - 49 Square Feet Wing Span - 24 Ft
Canard Area - 14 Square Feet Canard Span - 12 ft
Gross Weight - 870 lb
Empty Weight - 380 lb (VFR)
Two-Place Wing Loading 13.8 PSF
Pwr - Volkswagen or Franklin 60 Direct drive, prop mounted on

engine
Elevons on canard, no control surfaces on wing
Fixed main gear - airfoil-shaped, molded fiberglass strut.
Retractable nose gear - ball/screw assembly allows retraction/extension on the ground with crew in the airplane. Thus, the airplane "kneels" and parks on its nose.
Directional stability provided by Whitcomb 'winglets' with single-action rudder/speedbrake surfaces.
Only about 25% of the number of parts as in a conventional structure/configuration. Structural method allows maintenance of exact surface contour for even severe flight loads.
Flight surfaces are being contoured to within .003" per 2" surface waviness.
All performance estimates are being withheld - I refuse to claim estimates that I myself don't believe, and since this is now just a research project, I cannot answer any questions pertaining to it. Sorry.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

VariEze Wind-Tunnel Model

VariEze Prototype. Butt's dad, George, is holding wing.

VariEze Prototype in Front of RAF Headquarters.

Jerry Stewart received this letter and sketch from a friend:

"Dear Jerry, Have uncovered an obvious mistake in the design of the sportplane you are building. The rudders are supposed to be attached to the elevators - not the wings. (The designer was celebrating April first when he drew the plans.) Shifting the rudders to the rear (as shown) will also greatly improve forward visibility and will keep the plane from spinning wildly during flight. If you're in doubt about which way it goes - I suggest you start from the middle of the runway when you start your take-off run. Above all - remember to land just before the fuel gauge reaches full. (If the same guy designed your parachute, - you're in real trouble!)" **SKETCH OMITTED**

FLASH! World's first VariViggen gear-up landing.

The newsletter was held up to include the details of my first gear-up landing. It occurred during the air-show at the Corona regional EAA Flyin, May 4. N27VV gave airshow demonstrations on Saturday and Sunday for the flyin. On Sunday, I had completed the airshow demo, all except the landing; when I moved the gear handle down, I heard a different noise and noted that although I had electrical power to the main gear (transit light on) the mains did not come down. The failure was later determined to be the spring that connects to MG24 uplock arm. The spring had apparently been knicked with pliers when forming the hook on one end in 1970 when the spring was installed. Five years later, during the airshow demo, the spring broke. Without this spring, the

right main gear remained locked up. After several passes over the crowd, for inspection of gear position and some radio discussion with those on the ground on whether or not to land in an adjacent grass field, I decided to land on the main hard surface runway with the nose gear down. This was taking the risk that the nose gear would not fail and thus reduce the damage. I made a "full-stall"-type landing with engine and switches off and after a short roll/slide, I got out to inspect the damage. Damage was limited to one skid (VS1 extension with small wheel) a small scrape on one wing tip -(only one rivet damaged) and partial collapse of my centerline fuel tank. The tank remained attached firmly on its mount and did not leak. The nose gear took the 'slap down' load well with no damage. About 20 volunteers lifted the aircraft up while I scampered underneath to manually free the uplock and to lock the gear down. I then taxied back to a hangar, inspected the aircraft, elected to pin the main gear down and locked for the flight home and within 1 1/2 hours of the gear-up landing, I took off and flew it back to Mojave where I was greeted by 60-knot surface winds. Landing and taxi-in were uneventful despite the fact that at the time, two other aircraft were being jerked from their tiedowns and suffered wind damage much greater than my earlier gear-up landing!

I learned a bit from this experience:

1. Inspect uplocks during preflight and use appropriate quality control during their installation.

2. If faced with a main gear-up landing, pull the main gear circuit breaker, extend the nose gear and make a landing with the nose quite high (full flare) on a hard surface. This landing is really not more difficult than a conventional landing and you can expect very little damage.

3. Gear-up landings on VariViggens are far safer than on conventional aircraft where one of the first things to get damaged is the carb and fuel line and the possibility of a fire exists.

4. Note that the emergency extension free-fall system backs up an electrical failure and a mechanical failure of the electrical motor and gear box, but does not extend the gear with a jammed uplock. I do not recommend a design change of any type since the gear has had nearly 1000 satisfactory cycles during all types of weather and flight conditions. Any change now would be starting at zero experience with a resulting increase in risk.

5. Gearup landings have a very positive appeal from a marketing standpoint. It emphasizes how rugged the structure is (to survive with only minor damage) since we immediately received seven orders for plans from people who saw the landing!

NEWSLETTER SUBSCRIPTION - $4.75/year
OVERSEAS SUBSCRIPTION - $5.75/year
BACK ISSUES - $1.00 each

SKETCH OMITTED

THIS NEWSLETTER is being written in the last few days of hustling around, completing all the preparations for Oshkosh '75. The last few months we have really been busy with our new airplane's first flight only eight weeks ago and the new SP wings for the VariViggen being flown only a week ago. So, I hope you excuse us if the newsletter is a little short and somewhat disorganized.

We need a name for the newsletter! Now that the newsletter is being expanded to include the VariEze as well as VariViggen, our old name is no longer good. Please send in your suggestions, possibly a name using the word canard?

VARIVIGGEN SPECIAL PERFORMANCE WINGS

The new all-glass special performance wings for the VariViggen (see Newsletter #3) were flown for the first time on July 16. The performance improvement has been as expected: rate of climb at sea level, 1600-lb weight, is just over 1000 fpm! For rate of climb at altitude, add about 150 fpm to the curve shown in the VariViggen Technical Report. Cruise performance is higher, also. With the new wings and the new RAF-supplied cowling, the cruise speed at 8000 feet is 159 mph using the 0-320 engine at 75% power. The SP wings were flown both clean and with winglets. The winglets add directional stability, help the rate of climb at low speeds, and have no effect on the cruise speed.

What are winglets? Winglets are two vertical fins on each wing tip. They were designed by Dr. Whitcomb from NASA who previously developed the transonic area rule principle and the supercritical and GA(W) airfoils. VariEze, N7EZ, was the first aircraft to fly with winglets although hundreds of hours of windtunnel tests were previously conducted by NASA. The lower surface winglet extends from the leading edge back to 33% of the tip chord. This surface is cambered inward and is inclined 30 degrees out from vertical. The upper surface winglet extends from 33% of the tip chord aft. This surface is cambered

outward and is inclined 15 degrees out from vertical. Winglets are optimized to unwind the tip vortex to the greatest extent possible. This reduces induced drag, resulting in a 6% fuel saving. In addition, the local incidence of the surfaces are inclined to produce forward thrust which offsets the parasite drag of the vertical fins. This is possible due to the high amount of lateral flow near a wing tip. **SKETCH OMITTED**

The SP wings hold 18 gal of aux fuel, which increases max range to near 600 miles. This fuel is pumped into the normal fuselage tank by an electric pump. The tanks have flush caps and are filled individually. The weight of the new wings are about the same as the old, metal wings. The tiedown points have been moved to near the tip to allow more convenient attachment of the most common tiedown systems.

The SP wings use the same WA3 straps which are used on the metal wings. These bolt to a stub wood spar which is only two ft long. The rest of the spar is unidirectional fiberglass. The entire skin, trailing edge spar, and ailerons are glass/foam composite. No ribs are used. The SP wings were built in about 110 man-hours which is only 1/3 the time needed for the aluminum wings. Finishing time to obtain a first-class surface contour added about 30 man-hours.

A large number of photos were taken during the new wing construction for use in the SP wing plans. The plans will also show many details to educate the builder in the methods of structural fiberglass application. The plans will also include drawings of a foam/glass rudder. Thus, all the sheet-metal structure will be removed from the aircraft.

Flight tests have shown only a one-mph cruise speed change with reflex position, thus reflex control probably will not be required for a VariViggen with SP wings. I need to do more flight testing with the new wings before I decide on this for sure, but it looks as though we may recommend a fixed reflex and lengthening the nose gear about 2" to allow a slower nosewheel lift-off speed without the aid of up reflex. Rate of climb does not seem to change with reflex position when using the SP wing. All modifications required and details will be included with the plans. The wings will be "service tested" on the Oshkosh trip. We will start work on the construction drawings when we return. I expect plans availability by October.

We do not plan to stock the foam, since it is readily available from other suppliers. We will have the unidirectional fiberglass though, since it is not readily available in partial rolls. We will not stock the Shell epon epoxy resin, but we will refer you to several retail suppliers.

MORE ON WOOD ADHESIVES - I have received two separate reports from builders who have had poor results from the epibond resin recommended in the plans. Apparently the supplier has been sending out resin which is out of shelf-life or otherwise unsatisfactory. Until this is resolved, I recommend the use of only the epoxies shown in previous newsletters, rather than epibond.

VARIVIGGEN PLANS CHANGES - I can't really believe it, but since newsletter #4, I have received no notices of errors or improvements in the plans! Is everyone asleep or have we finally weeded out most of the corrections? There are important plans changes in the last four newsletters. VariViggen builders who do not have these, should purchase the back issues ($1 each; no charge for Newsletter # 1).

VARIVIGGEN FUEL TANKS AND ENGINE MOUNTS - Vernon Williams (s/n 189) has made five fuselage fuel tanks and will have them on display and for sale ($175.) at Oshkosh. The tanks are excellent quality and include the filler neck and finger strainer. He has also produced dynafocal-type engine mount for his VariViggen and may be talked into making one for yours. Contact him directly - #4 Southmont Circle, Little Rock, Ar 72209.

VARIVIGGEN KICK-IN STEP - VariViggen prototype, N27VV, has been equipped with a kick-in step to allow front cockpit boarding without the ladder. This was a relatively simple modification requiring only about three man-hours. The following sketch is self-explanatory. The shorter-legged pilot may want to move the step up about three inches to easily allow his leg to swing over the side. **SKETCHES OMITTED**

VARIVIGGEN INBOARD WING RIBS AND BULKHEAD KITS - Our apology to those who ordered these items at the availability date noted in Newsletter 4 and then waited over six weeks for delivery. Our supplier was unable to meet his initial estimate and when the first kits were inspected, several changes were required. All back orders should have been shipped by 22 July. The bulkhead kits also include F5, F7, F8, F9, and F18 pieces, as well as excess plywood.

VARIVIGGEN CONSTRUCTION MANUAL - Part One of the construction manual has been in stock since June 26. The manual with its many photos is proving to be very beneficial, particularly to the first-time builder. Part One does include landing gear construction, but is not as detailed in this area as it should be. More landing gear construction information will be included in Part Two. The construction manual will not cover the outboard wings, since these will be well photo documented and the procedure will be detailed in the SP wing plans.

NEW PRODUCTS AVAILABLE FROM RAF -

VariEze Information Kit - includes approximately 4000-word description, 14 photos, and one 8"x10" glossy, all specifications, performance charts, homebuilt program, etc. $5. - includes first class mail ($6.00 Overseas).

VariEze Embroidered Jacket Patch - Tri-colored; VariEze planform - $1.95 each.

BUILDING TIPS - If your wood pieces do not fit perfectly for gluing, merely mix asbestos fibers (available from Gougeon Brothers, 706 Martin St., Bay City, Mi 48706) in to thicken the epoxy, so it will not run out of the gap. Structural joints can be made with gaps as great as 1/16" and non-structural "fill-ins" can be done up to 1/2".

SHOPPING - Partz Corp., 1232 W. Main, Owosso, Mi 48867, (517) 725-8565 will anodize approximately 100 small alum. fittings for $15.00. Suggest certified mail, return receipt requested, if you mail your parts to them.

LOOK FOR ANOTHER VARIVIGGEN ARTICLE in "Science and Mechanics" magazine - on the newsstand after September 30.

The following is the schedule of forums at Oshkosh '75 by Burt Rutan:

Design Forum - Friday
VariEze - Saturday
VariViggen - Sunday

VARIEZE COMPLETES 95-HR FLYING -
TO BE OFFERED AS A HOMEBUILT IN 1976

The VariEze prototype, N7EZ, has been logging a lot of flight time for such a new prototype. It made its first flight on 21 May 75 (almost exactly three years after the VariViggen prototype). The initial test program was completed on 8 July and the area restrictions were lifted. Since then it has been flown to the Hollister fly-in here in California, and on a 1000-mile round trip to Tucson, Arizona.

The back seat has been fitted with a temporary long-range fuel tank for the distance record attempts. Dick Rutan, Burt's brother, plans to fly N7EZ nonstop from Mojave, Ca to Oshkosh, Wi on 1 Aug 75. Then, within the next week, an official FAI/NAA closed-course distance record attempt will be made. Look for an article and the VariEze on the cover of the September issue of "Air Progress."

The VariEze was designed for maximum cruise economy. It can demonstrate 70 mi/gal with 30% power at 135 mph; at maximum cruise speed with 75% power, 48 mi/gal can be obtained at 185 mph. Climb performance for the Volkswagen-powered two place is 1200 fpm at 880-lb gross weight (two people, 1000-mi range), and 1800 fpm at single-place weight of 625 lb. The aircraft can carry two 6-ft, 4-in people and two specially designed suitcases.

The name, VariEze (pronounced, "Very easy"), refers to the aircraft's ease of construction: The prototype was built entirely from fiberglass in composite form using rigid foam as core material, and simplicity was the key in structural/system design.

This fall, the VariEze prototype will be making assaults on the following FAI World Records in the under 500-kg (1102-lb) weight class:

RECORD	NOW HELD BY	CURRENT RECORD	ESTIMATED VARIEZE CAPABILITY
Distance In A Straight Line	Kaarlo Heinonen Finland HK-1	1767 Mi	4400 Mi
Distance	Ed Lesher		

In A Closed Circuit	USA Teal	1554 Mi	4400 Mi
Speed For 2000 km Circuit	Ed Lesher USA Teal	142 mph	185 mph
Speed For 1000 km Circuit	Ed Lesher USA Teal	169 mph	235 mph (Turbo Charged)

Several changes were made during the initial test program. The pitching moment of the main wing was too great, which transferred too much load to the canard. This was temporarily corrected with metal tabs taped to the wing trailing edge and later permanently corrected by a change in the main wing airfoil. The original canard configuration may have been susceptible to flutter. A modified canard with distributed, overbalance weights has corrected this. The canard uses the GA(W) airfoil which has not performed as well as had been expected. Its chord is only 14 inches, thus at stall, the Reynolds Number is only 500,000. The GA(W) airfoil has very poor lift below 750,000 Reynolds number. This results in a higher than desired stall speed (55 to 60 kt) and poor roll rate below 70 kt. I have located data for an airfoil designed for high lift at the low Reynolds number. After Oshkosh I plan to build another canard for N7EZ using this new airfoil. It will have a low trailing edge camber, thus the external trim tabs will not be required.

We plan to market construction drawings and components for the VariEze in the spring of 1976. Tooling will be constructed this winter for the production of homebuilt components (canopy, cowling, forward seat/bulkhead, main wing spars and centersection spar, molded glass landing gear, and machined parts). The first parts from the tooling will be used to build another VariEze here at RAF. This will absolutely prove the tooling accuracy. This construction project will be photo documented and those photos will be used in the construction plans.

We have received very few builder's suggestions since Newsletter 4. If you have found a "better way" to do something, let us know and we'll pass it on to other builders. Also, if you have questions about the VariEze which are not in the information package or here, send them in and we will answer them in the next newsletter.

NEWSLETTER RENEWAL - When your newsletter subscription has expired, a notice will be placed in with your last issue.

SEE YOU AT OSHKOSH!

SKETCHES OF VARIEZE AND VARIVIGGEN OMITTED

THE NEWSLETTER NAME, formerly "VariViggen News," has now changed. The suggestion of "Tail Pusher" was sent in and we modified it to "Canard Pusher." A special thanks to that person, whose name we don't have, and who gave us the idea. Ken Ashdown's suggestion of "Canard Line" ran a close second to being picked for the newsletter name. We received many, good suggestions - thanks to all who contributed. The following list are a few of those which we thought would make interesting reading: The Canard Line, The Canardian Club, Vari New-Z, Canard Time News, The Vari Forum, VariUnique Aircraft News, Canard Capers, Canard Contrails, Glass Backwards News, Vari Vignette, The Canard Rumor, Canard Disclosure, Canard Gas Line, Canard Trend, Canard Courier, The Backward Flyer, The Canard Leader, On the Nose, Canard Tales, Canard Forward. The new name should last for some time now, until we come up with an aircraft without a canard!

RAF ACTIVITY has been brisk since the July newsletter. More tests have been completed on the new SP wings for the VariViggen. Carolyn and I flew the VariViggen to Oshkosh, including a trip to Kentucky on the way back to California. My brother, Air Force Lt/Col Dick Rutan, flew the VariEze to Oshkosh. His attempt to make the 1800-mile trip non-stop was cut short 300 miles from Oshkosh when he made a precautionary stop due to rising oil temperature. He made the 1500-mile leg in eight hours, 50 minutes for an average ground speed of 170 mph. Engine oil problems aborted a Saturday attempt to set a distance record, and the engine was changed over night. On the last day, August 4, of the EAA convention at Oshkosh, Dick set a new World's record for closed-course distance. He flew a total of 13 hours, 8 minutes; covered an official distance of 1638 miles - actual distance was about 1660 miles. Average power setting for the flight was approximately 40 to 50% power. The 1700-cc VW engine used 38.4 gallons of fuel. Dick had an uneventful flight back to his home in Tucson, Arizona the day after the record flight: he averaged about 155 mph on his trip home at approximately 60% power, and obtained approximately 53 mpg at 10,000-ft altitude. I understand that a detailed story of the VariEze's activity at Oshkosh will appear in the October issue of "Sport Aviation." So enough said - read your magazine. Carolyn and I gave the VariViggen SP wings a real

shakedown by taking the Denver - Las Vegas route home, instead of the Albuquerque course normally selected in the summer due to the high altitude. The VariViggen performed well at the required density altitude of 16,000 ft crossing the Continental Divide. True air speeds as high as 159 mph were obtained at a cruising altitude of 7500 feet. After returning from Oshkosh the VariViggen and VariEze logbooks showed 550 and 130 hours, respectively. The VariViggen did not fly as much at Oshkosh this year as it has in the past due to our time constraints with the VariEze record attempts. However, rides were given to Jack Cox of "Sport Aviation" and Don Dwiggins of "Plane & Pilot" magazines.

We were extremely pleased to be presented the "Outstanding New Design" trophy for the VariEze. This is the same award garnered by the VariViggen in 1974. This year RAF had a booth to display plans and components for the VariViggen and to answer questions about our up-coming VariEze program.

George Mead has joined us this month. He is a capable engineer with extensive practical light-plane experience. He will be helping on both the VariViggen and VariEze programs. Many of you met Gary Morris at Oshkosh - he is as much an artist (he did the art work for the masthead) as a craftsman in fiberglass work. (Another big accomplishment was Gary having his hair cut!)

FLASH - It's now official; VariEze World's distance record has now been certified and registered in the list of official F.A.I. Records

CP06, Page 1

VARIEZE PROGRESS REPORT - The most important news is that we have definitely solved the deficient low-speed roll rate and have lowered the stall speed by eight knots. I really wasn't too confident that the new canard with its new airfoil and elevon would make enough difference in roll rate at low speed. Before the new canard was ready for flight tests, I had made a detailed design study of a control system which included conventional ailerons on the rear wing. Those drawings are now in the trash can: we are keeping the canard elevons, the clean wing, and the super simple control system. The aerodynamic improvement with the new low-Reynolds number airfoil and slotted elevon is the most dramatic change I have seen occur without a major planform revision. Not only did the maximum lift increase by over 50%, the slope of the lift curve was increased by 30% changing the once "nose heavy" feel and high stick forces to a too-sensitive condition. I subsequently reduced the new canard's area and revised its elevon balance point to obtain what I now feel are near optimum. The new canard does not have the external trim tabs on the elevons.

With the old canard the aircraft would exhibit a nose-down stall break at 58 to 60 knots. With the new canard the aircraft can be flown at full aft stick at 52 knots and at a much greater angle of attack. Also with the old canard, roll-rate capability degraded below 80 knots and rudder control was needed for adequate roll below 70 knots. The new canard elevons result in roll performance very similar or better than the average light plane. A 60-degree bank change can be accomplished in less than three seconds even below 60 knots and roll control is adequate even at 52 knots. I have landed the airplane several times in

the relaxed cruise position, with my feet in front of the rudder pedals. The overall maneuverability has been greatly enhanced.

I don't yet know if the VariEze will have the same low susceptibility to stall/spin as the VariViggen. It is possible but I won't know until all tests are completed. I do not plan spin tests on the prototype, N7EZ. The homebuilt prototype will be equipped with the appropriate instrumentation and recovery devise and a complete spin-test program will be flown before the construction plans are released.

The initial printing of the VariEze information kit stated that the aircraft was capable of 70 mpg at the economy cruise speed. This was based on flight test data at 10,000-feet altitude in which we obtained 61 mpg without a mixture control. Using standard corrections it was calculated that the carburetor was full rich and that 70.5 mpg would be obtained once a mixture control was installed and leaned to best mixture at 10,000 feet. It was later found that the carburetor was already jetted too lean and thus, only about 62 mpg can be obtained. The following table now appears in the information kit and shows the current estimates for a homebuilt VariEze.

VARIEZE PERFORMANCE TABLES OMITTED

VARIEZE HOMEBUILT PROTOTYPE

Many people have asked why we are building a second airplane; why not just sell plans for N7EZ? First of all, N7EZ was built without any tooling. Tooling will be required to build the following parts for the homebuilt kits: wing quick disconnects, cowling, main and nose landing gear, and canopy. We are building an airplane from the first parts to come from the tools; thus it will be assured that the parts will fit properly. Secondly, N7EZ was designed around the lightest (140-1) version of the VW engine, to maximize the amount of fuel which could be carried for distance records. It has become obvious to me that many people will insist on heavy accessories and will want to adapt the Continental series aircraft engines which can weigh as much as 197 pounds even without starter and with a a light alternator. This heavy an installation would not be practical for N7EZ.

When comparing engine price based on 1200 flight hours, the price of the aircraft engine becomes quite competitive with the lower cost, less durable VW conversions. My own experience, though quite limited (N7EZ now has 160 flight hours since first flight last May), points to the advisability of paying the higher initial costs for a definitely reliable powerplant. This is not to conclude that the VW cannot be converted and operated reliably by an experienced individual using aircraft-quality components and proper installation practice. There are available, however, conversion components and built-up engines which are not thoroughly proven and are not up to accepted aircraft reliability standards. For this reason I am making relatively major design changes which will allow installation of engines weighing as much as 198 pounds, and thus, make it possible to adapt Continental aircraft engines.

The homebuilt prototype will have a Continental 0-200B engine (100 hp) which I estimate will climb nearly 2500 fpm and cruise 210 mph at 75% power. The C-90, C-85, C-75, and C-65 Continental engines will also be ideal. The empty weight of the 0-200-powered aircraft will be about 480 lb, gross, about 980. A 1700 cc to 2100 cc VW conversion can also be adapted. Empty weight of the VW-powered aircraft will be about 430 lb, gross, about 880 lb. The additional wing area and stronger landing gear needed to provide for the heavier engine will compromise the cruise speed of a VW-powered aircraft, but by only four to seven knots. Do not write us at this time for advise on the VW engine. We will not be in a position to make any recommendations until the plans are available. I plan to keep flying N7EZ as much as possible to gain more experience with the VW installation. After some modifications we will make an assault on the straight-line distance record with a San Francisco to Miami flight (2600+ miles, including extensive night flying), possibly this fall/winter.

Additional changes being incorporated in the homebuilt prototype include

1. shallower fuselage and taller canopy to improve downward visibility over the side

2. roll-over structure

3. longer nose and locations of instrument panel further forward to allow knees to be placed forward after sitting down

4. more room in the back seat and more baggage room

5. instrument panel which can house NAV COM, transponder, eight 3-inch instruments plus all engine instruments. This allows IFR equipment without need for the expensive miniature primary instruments.

6. revised side-stick control configuration which greatly improves human factors and further simplifies control system (don't call - we cannot release details yet).

7. fuel capacity increased to 20+ gallons

8. increased aspect ratio on canard

9. improved nosegear retraction mechanism (N7EZ's nose gear retracted during landing rollout at Oshkosh probably due to inadequate down-lock indication - damage was minor.)

10. larger maingear tires and improved brakes (N7EZ had difficulty taxiing through the larger ruts off the runway at Oshkosh).

11. elimination of plywood formers - these are being replaced with glassed high-density PVC foam, thus saving 4-lb weight and eliminating any possibility of deterioration

12. further simplification of the fuel system

13. use of special resins in landing gear to eliminate slight tendency to creep

14. further simplification of the structure and about a 5% reduction in the number of parts. We are confident that the airplane can be constructed in 400 to 700 man-hours from to-be-available components and materials.

The wing-disconnect system will not be as shown in the VariEze information kit. We found that production of the three-piece glass spars would be too expensive. In the interest of keeping kit price as low as possible we are using a machined assembly at each wing attach point. Half of the assembly is installed on the wing during wing construction. The other half is installed on the center spar during its layup. Removal of each wing for trailering will involve removal of two bolts, each holding two large taper pins. Removal of the canard is by two shear bolts reached through the cockpit rather than by the two external tension bolts previously used on N7EZ.

While the larger main tires will improve rough field operation, it is not yet known whether routine operation from other than smooth surfaces will be advised. I will have an answer on this by the time the plans are available. I do not plan, though to compromise the efficient high-speed cruise to provide rough/soft field capability.

VARIEZE TO BE OFFERED AS COMPLETE KIT

The VariEze info kit explains that RAF will make available the machined parts and several components such as landing gear, canopy, cowling, and wing fittings. We are, however, now working with several companies to supply portions of all the materials required. The selection of these companies is being based primarily on their delivery history - for example the company which will be authorized by us and supported by us from an engineering standpoint to supply the foam kit, will be the one which we think will be most likely to provide prompt, quality delivery of the foam. We must work directly with them, since it is essential that the proper type and amount be used and that they respond immediately to any engineering changes.

It would be unwise for RAF, itself, to expand to produce the entire kit, since it would take years to attain the efficiency of established companies in a variety of parts and materials. The fiberglass cloth, previously available only from Europe will be woven in the U.S.A. and distributed by a company equipped to deliver. When the customer receives VariEze plans, he will be referred to specific U.S. companies, authorized by us and who have our engineering support, to purchase the following kits or individual items: 1. machined parts, 2. foam kit which consists of three types in five different densities, 3. glass, epoxy, flox, and microballoons, 4. hardware, 5. landing gear, 6. canopy, 7. cowling, 8. finishing materials. It may seem awkward to deal with three or four companies to obtain a complete VariEze kit, but this is not the case, since each is selected for its record of capable and prompt delivery service. Each company selected will not only receive our continuous engineering support but must live up to our contractual delivery schedules.

Only two of the eight kit areas have been specifically selected at this time. If you are a good, established company, currently handling any of these type items, and would like to supply kits, please contact us.

BUYER BEWARE - Buying the wrong fiberglass, epoxy, etc., can be the same as using conduit to build a steel-tube airplane instead of 4130. Remember, the years of testing and flight experience of glass aircraft points to a very important fact: You must use the correct materials. True, it is possible that another product could do the job, but to verify this would mean starting from zero with tests for strength, workability, weight, compatibility, exposure to environment, etc. Since we do not want to take years more to develop the structure, we must insist that the builder use the products we will specify in the plans. Do not buy any product now. We have already had companies indicating that their products can be used on VariEze construction without having even a grasp of the structural requirements!

QUESTIONS/ANSWERS ABOUT THE VARIEZE
The following are some answers to questions asked about the VariEze. If you have further questions, write them down and send them in and we will answer them in the next newsletter. Do not visit RAF expecting to see N7EZ or anything related to the VariEze. We have been working at low efficiency recently because of the flood of visitors. N7EZ is shown only when it is out of the hangar, flying - otherwise we have to keep it locked up so we can work. We cannot answer questions individually which aren't answered here or in the VariEze information kit. This policy will change as soon as we have the plans on the market - after that time, you will be welcomed to come up for a flight demo/ride, structural demo, construction methods demo, etc. We just can't afford to demonstrate something we aren't currently selling.

1. Isn't the small cockpit cramped? No, in fact the seat has been very carefully engineered for long term comfort. Dick found more discomfort with four hours in a Cherokee than 13 1/2 hours in the VariEze. I've spent as much as seven hours per day in it without even wanting to get out to stretch after landing. The comfort is obtained by a combination of the high thigh support, lumbar support, and correct height of arm rests, which relieves the back. The variety of foot/leg positions and ability to trim hands-off for long time periods, also adds to comfort.

2. Is cockpit heat required? No, due to the excellent insulation provided by the composite structure, the canopy will even keep the feet warm. Cold night flying is generally rare enough to not justify a heat system.

3. What is the glide ratio? At idle power (close to zero thrust) and 72-knots airspeed, glide ratio is 18.8.

4. Are dual controls planned? No. Again, I do not plan to compromise the design simplicity to do a mission other than that of efficient cruise. Learn to fly in an airplane which was designed as a trainer. Dual controls would triple the number of parts in the control system and eliminate one suit case. Also, controls could be jammed when flying solo with baggage in the back seat. Currently there is nothing in the back seat which moves (except Carolyn). Four pilots

have been successfully checked out in N7EZ - none of them had side-stick experience.)

5. Is the VariEze an aerobatic airplane? No, providing for that capability would mean compromising the design goal of best efficiency at high-speed cruise. However, it does appear that the basic aerobatic maneuvers will be satisfactory. By the time the plans are available, I will list any allowed maneuvers and limitations.

VARIVIGGEN WEIGHT AND BALANCE METHOD

Since several VariViggen builder's are getting close to first-flight time and will be needing to do an accurate weight and balance, the following is provided to add some details not shown in the plans:

Materials Required - Three scales, two must be capable of weighing up to 500 lb, the other can be a bathroom scale - although I've seen someone do a reasonable job with five bathroom scales, placing a board (weight of board subtracted later) between pairs of two for each main wheel. (Borrow the scales!) Assure that the scales are accurate - test each with a known weight in the expected range. Caution on low cost bathroom scales - you may have to make a board to distribute the load to prevent warping the table, which will give an inaccurate weighing. You will also need a level, plumb bob, 12-ft tape measure, and chalk line. The average VariViggen will need nose ballast to sit comfortably on its three gear in a level attitude. Place a known weight at a known fuselage station - 50 lb in the front seat at F.S.60, for example.

Level the aircraft, using a carpenter's level on the flat bottom of the wing. Adjust it down by bleeding the air from the nosegear strut or up by placing a block under the nose tire. Now take the plumb bob and mark a point on the floor corresponding to each maingear axle centerline and both sides of the nosegear axle centerline. Use the plumb bob to mark a line on the floor corresponding to a known fuselage station - the most convenient is F.S.19.75, holding the plumb in line with the joint of the nose cone and the forward edge of F20. Now move the aircraft and make chalk lines on the floor as shown between the mainwheel reaction points, the nosegear points, and the two F.S. 19.75 points. Measure the distance between F.S.19.75 and the nosegear and maingear action points, for example 8.05 in and 110.15 in making the nose gear at F.S.27.8 and the main gear at F.S.129.9. **SKETCH OMITTED**

Now, get the help of a couple of friends to lift the wing tip while you slip the scale under each main wheel, one at a time, and a scale under the nose wheel. Recheck level attitude and read the scales - tap them to be sure friction is not effecting the readings. Remove the aircraft and record tare weight - chocks, boards, etc. Now setup the following table - be sure to state status of equipment. Note that ballast weight and moment are subtracted.

LOCATION	GROSS	TARE	NET	ARM	MOMENT
RT MAIN	481	+2	479	129.9	62,222
LT MAIN	497	+3	494	129.9	64,170

NOSE	12	+1	11	27.8	306
SUBTRACT BALLAST			-50	60	-3,000
TOTAL EMPTY WT			934		123,698
EMPTY CG =			123,698/934	=	132.44

You now know the empty weight and empty cg and are ready to calculate your weight and cg for your first flight. Assume you weigh 175 lb, your parachute weighs 18 lb, and you will carry 25 gallons (150 lb at F.S.137) fuel. Make up the following table:

DATE 25 SEP 73
VARIVIGGEN N15VV
S/N 394
FUEL DRAINED TO UNUSABLE
OIL 6 QT
NARCO XYZ RADIO
BASIC INSTRUMENTS

	WEIGHT	ARM	MOMENT
EMPTY AIRCRAFT	934	132.44	123,698
PILOT	175	62	10,850
CHUTE	18	64	1,152
FUEL	150	137	20,550
TOTAL	1277		156,250

cg= 156250/1277 = 122.36

Now, checking on page 3 of the plans, a cg of 122.36 is within the envelope suggested - so follow the maiden flight procedure in newsletter #2 and happy flying.

CP06, Page 5

VARIVIGGEN SPECIAL PERFORMANCE WING

The new composite outer wing panel for the VariViggen has been flown about 80 hours now. The performance figures stated in newsletter #5 are accurate and the structural durability is excellent.

We are now working with various suppliers for foam, epoxy, and glass, so there should be no problem obtaining any of the materials. The SP wing plans will be available the first week of November, but we won't know the price of the plans until October 22. Those who need the plans before the January newsletter can contact us after the above date to receive further information. Complete details will be in newsletter #7 for those who won't need them before January. The special unidirectional fiberglass which is being woven for us, will be available by mid December. Those who will need it before then can contact us and we can supply a substitute from our stock. Please don't unless you absolutely need it right away, since we're not presently equipped for a large volume. The price will be much lower after the manufacturer weaves the large order.

Should your VariViggen have the SP wing? The decision is yours. Personally, I like the extra climb, cruise performance, and lower rate of sink, but the roll rate is lower and the stall margin is less. Tuft tests have shown some stalling of a small amount of the SP wing near the tip at less than 47 knots - this is very close to the minimum

attainable speed. This tip airfoil separation results in a slight buffet and "wander" in pitch and roll when near and at full aft stick. Full aft stick can be maintained with power for level flight (or greater) without any stall break or roll-off, and roll control at full aft stick is good. However, the aircraft doesn't have as solid a 'feel' as the standard wing below 50 knots. Accelerated stalls (in a turn) are smooth and solid with power settings of 2100 rpm or more. Accelerated stalls with less power do result in some bucking and slight wing rock.

In one instance, George Mead experienced a 1/2 snap roll as he was pulling up from a dive and rolling. This occurred during simulated air combat with the VariEze. I haven't done a complete spin program with the SP wing, so I don't know if it could be spun. This brings up another point: Someone mentioned to me at Oshkosh that he was flying his radio-controlled model VariViggen (I assume with the standard wing), and he experienced a spin which was entered when the engine quit in a turn and was not recovered. This is baffling to me, since my spin test model would not spin, regardless of the control or throttle inputs. At least 75 spin attempts were made. Also the full-size aircraft can maintain full spin controls indefinitely without spin entry. In fact, for airshows I have done a pass by the crowd many times with full rudder and full aft stick at low altitude. I asked the gentleman, who's name I don't have, to send me a complete report of the models configuration, incidences, cg, and control deflections, but I haven't heard from him yet.

Now back to your decision. While the SP stall margin is less, the airplane is still quite resistant to stall during normal flight maneuvers, is very maneuverable at low speed, and quite safe. I strongly recommend the SP wing for those installing 125-hp engines or those with 150-hp engines who plan to routinely operate near gross weight, from short fields, or at high density altitudes. The additional stability provided by the winglets also improves high-speed flying qualities. If you don't plan to operate heavily loaded and like the fighter-like roll rate and extra stall margin, then select the standard wing.

In newsletter #5, I passed on to you some preliminary thoughts regarding reflex and nosegear length with the SP wing. First, concerning the nosegear length, I do not recommend lengthening the gear to obtain lower rotation speed. The maingear position (F.S.129.8) is already moved approximately 1 1/2" forward of that on N27VV to lower the rotation speed and lessen the load on the nose gear on rough fields. I think that lengthening the nose gear would make the airplane too difficult to handle when sitting on the ground without someone seated in the cockpit. It would take more load to hold the nose down before getting in and would make that first step too high.

I do recommend that you retain the variable reflex with the SP wing. You will find the up-reflex helpful to obtain minimum ground run for short fields and having the reflex down or neutral adds more stall margin for the aft wing. If you are a nut for simplicity and aren't planning short field operations, you can disregard the reflex. Merely rig the neutral-aileron position of the AB8 belcrank to the zero reflex position shown on page 40 of the plans. The SP wing plans will show you the correct reflex of the aileron.

VOR ANTENNAE LENGTH
Someone told me that the 14-inch length VOR antennae should be 16.6"; another said 26" but it depends on the balun, or coax loop. I have the system shown on the plans on N27VV and I get excellent accuracy and about 80-mile range. Is there an antennae expert out there who would like to write a blurb on homebuilt VOR antennaes for a future newsletter??

VARIVIGGEN BUILDING TIPS
Fit of F41 Bulkhead to F27 Visor - A previous newsletter suggested that you leave excess plywood on the top of F41 to fit it to the RAF-supplied F27 fiberglass visor. The following drawing shows the F41 contour required to fit F27: **SKETCH OMITTED**

Wayne Koch reports that the gear on the Ford window-motor assembly is a 9-tooth, 12-pitch 14 1/2-degree gear, and that the extra gear shown in newsletter #4 can be eliminated. This is true only of the Ford, not the Dodge motor. A Boston #ND30 will mesh directly with the Ford motor and provide the correct ratio for the nose gear. For the main gear use a Boston # ND64. Unfortunately the 12-pitch gears aren't available in a light narrow flange variety, however, the 3/4-inch flange can be turned down to save room and weight. The following drawing shows how the 5.5" dia. main gear can be mounted to clear the aileron cable. Photos will be available with the 2nd part of the construction manual. **SKETCH OMITTED**

Be sure to follow the order shown on the plans when rigging the main gear. First, adjust pushrod MG6 to obtain correct down lock action. Then retract gear and position the correct over center position of MG5, adjusting the uplock action with the uplock turnbuckle. Then drill MG14 into MG12 and install bolts through MG14. Extend gear and accept the extended position.

The following are tips sent in by Jim Cavis concerning the main gear. "When welding pivot on MG16, put a bolt through it so it will keep its shape. After making and drilling MG16, use it as a guide to drill through spars. Cable can slip on MG42 unless it is passed through spool like on nose gear. Once this is done, you can't get the cable and MG42 through the holes in the ribs. I made my cables up in three sections, so motor and MG42 can be removed without removing MG9 pulleys." **SKETCHES OMITTED**

"I used a 5/8"x.125 steel tube for MG36. I tapped the end and used a fabroid 77330 rod end threaded into the end in place of the Heim HF-5C (plans page 47)." Jim also made an acceptable substitution to the MG20 bracket. Instead of bolting to WR46 rib and the spar, he just bent up two aluminum angles (top and bottom of pulley) and bolted them to the spar. **SKETCHES OMITTED**

Bulkhead Assembly - Remember, if you are assembling the bulkheads from several parts rather than cutting them out in one piece (to save plywood) you don't have to make scarf joints - just overlap the pieces, giving at least 3 square inches of overlap at each joint. This applies

to the bulkheads sold by RAF. The bulkheads are sized to provide sufficient glueing area to the skin and are much stronger than they need to be for all other loads.

Inclined Bulkheads - Use a plumb bob from the bulkhead tops to the jig to check incline. This assures an accurate slant. If the F121 bulkhead is not slanted enough, the F28 tank cover may not fit. If this is the case, you can knock the bulkhead loose from the stringers and move it back, provided you haven't already skinned the fuselage sides.

Maingear Rigging - If you move the pivot for MG5 and MG9 pulley to B.L.34.15 as suggested in newsletter #4 (when using RAF-supplied MG4) you may have to bend the uplock belcrank (MG29) outboard more and cut away a portion of rib 36.5A for clearance.

VARIVIGGEN GEAR-UP LANDING SAGA #2 & #3

On our way to Oshkosh this year, Carolyn and I again were faced with having to land N27VV with the main gear retracted. We landed on a hard surface runway with the nose gear extended. We got the prop stopped before touchdown and slid out on the rear skids and nose gear. Again, the nose gear took the load with no damage; all damage was limited to the two aft skids and a non-critical scrape on the aileron control arms. Inspection revealed the problem to be the same uplock spring which caused the gear to remain locked up three months earlier at the Corona flyin (see newsletter #4). We were on our way that afternoon again, after pinning the main gear down, and flew the remainder of the trip to Oshkosh with the main gear down. The next day at Oshkosh we repaired the skids and rerigged the main gear to put it back in operation.

This time the uplock springs loop had somehow slipped out of the bracket rather than failing like it had at Corona. The spring loop was returned to the bracket, this time twisting it backwards so its own torsion wouldn't tend to remove it.

I feel quite embarrassed by having this spring fail - twice! After all, a spring is something to trust, like gravity. I am recommending that you install a simple addition which consists of adding a branch to the existing emergency extension cable. The present emergency extension cable removes the electric motor from the system, allowing the uplock return springs to push the gear overcenter so it can freefall down; this only backs up a failure of the electrical motor, and cannot extend the gear if the uplock springs fail or if the uplock would jam. By simply adding cables to the existing emergency cable and routing them to the top of the uplock belcranks, the emergency handle would not only remove the motor, but would pull the uplocks out and force the gear overcenter and on its way down. Thus, the emergency handle overrides a spring failure and any jam of the gear. The following drawings show how this is done:

Rig the cables so the motor is removed first, then a further pull of the handle forces the uplocks out and the gear down. **SKETCH OMITTED**

Gearup landing #3 - This one is of no real concern to builders, since it does not involve a problem which can occur with your aircraft, since an obvious design improvement was incorporated into the plans before they were first released. The failure allowed the MG5 bolt to slip past the MG29 bolt during gear retraction. As such, the microswitch on MG29 was not activated and the gear motor continued to run, jamming the gear way over center and failing the cable. This failure occurred on the third flight of the day at the EAA Western flyin at Tulare, California; with Bob Eldridge in the back seat, I had taken off to compete in the spot landing contest. Since there was a lot of activity on the runway at Tulare, we decided to fly to another airport about 20 miles away to do our gear-up landing there. The landing on the nose gear and aft skids was uneventful (routine?), the gear was fixed and we flew back to Tulare to compete in the spot landing contest.

NOW - I don't expect to hear from any more of the VariEze fans about wanting to retract the main gear!

Surface Finish - There are many acceptable ways to apply finish over the external wood skin. The following is the procedure used on N27VV: The wood is sanded with 80 or 100-grit sandpaper on a hard block, taking care to level areas around skin splices. Mix up a mixture of epoxy and microballoons (available from Gougeon Brother) and trowel into low places, fill gaps around joints, and form a 1/2" radius at the wing-fuselage and wing-vertical stab junctions. When dry, sand again. Apply the lightest available ceconite (available from Stitts); I think its 1.7-oz weight. Shrink down smooth and apply two or three coats of dope to fill the weave. Be sure to run the ceconite around easily-damaged areas like trailing edges. Sand when dry with 220 grit. Apply two coats of lacquer primer/surfacer (Dupont or eq), wet sanding after each coat with 320 grit. Finish by spraying on your favorite color Dupont Dulux enamel. Finish internal wood surfaces with epoxy as shown in the plans.

The glass SP wings are finished differently. Finishing details will be supplied with the plans. Remember if you use the glass SP wings, they (like all glass sailplanes) must be painted white. This keeps the glass resin below 120 degrees even in the hot sun and prevents it from losing its stiffness. An alternative is to use a high temperature phenolic resin in constructing the wings, but that can triple the resin cost. (For the same reason all VariEze aircraft will be all white, with a limited amount of trim color.) We are testing a polyester white finish which can be sanded and buffed the next day after spraying. More details on this later.

If anyone has wood aircraft finishing suggestions, send them in for future newsletters.

VARIVIGGEN PLANS CHANGES
Be sure to incorporate these revisions into your plans now.

Location PL - Plans
TR - Tech Report
NL - Previous Newsletters

CAT - Catalog
Category of Change
MEO - Minor error or omission
OPT - Optional improvement
DES - Desirous change - does not effect flight safety but should be incorporated to improve aircraft or correct a fault
MAN - Mandatory change - must be incorporated as safety of flight is affected

Category	Location	Change
MEO	PL pg 52	Nosegear door attaches to F32, not F20.
MEO	PL pg 14	View BB (from page 13) should not show C6 on the aft side of the forward spar. C6 is not required on the aft side outboard of B.L.24. See top view.
MEO	PL pg 13	The four bolts which attach canard spars to bulkheads are at W.L.22.85, not W.L..85. Be sure to epoxy, as well as bolt the canard to the bulkheads.
MEO	PL pg 25	SPAR D - The solid line drawn between the W1 gussets on the left should be erased - its presence indicates a spar web which isn't there.
MEO	PL pg 37	F.S. of trim pivot is 35.6, not 135.6.
MEO	PL pg 4	Aluminum tube - RM1 is fabricated from an aluminum bar, not from standard tube stock. Erase it from the tube bill of materials.
MEO	PL pg 25	Spar F butts to WS28, not to WS29.
MEO	PL pg 38	SA1 square tube forward end is at F.S.54.2, not F.S.154.2
MEO	PL pg 51	Upper left of page, MG20 center of pulley is at W.L.5.0.
MEO	PL pg 41	Faded words to left of brake master cylinder read "1/4" bulkhead fitting through F31-AN833-4D".
MAN	PL Chapter 19	Add the modification shown in this newsletter to expand the capabilities of the emergency maingear emergency extension system.

SHOPPING
If you are having trouble finding the DOAN#31-2014 rubber shocks, it may help to know that they are also listed as American Parts #2-2014 or Borg Warner #31-2014 or Anchor #31-2014.

I understand that a substitute for the Stanley 61-112 is a Lufkin # C9212-X. This is available at most surveying supply houses or through Robert Lamishaw - Lamco Enterprises, 3660 Wilshire, L.A., Ca. 90010. Also Francis Falejczyk, 7881 Seneca St., East Aurora, N.Y. 14052 says he has decimal 12-foot chrome cload tapes for $5 - postage included. Be sure you get one graduated in inches and decimals (10th & 100ths) of an inch. I've seen some rules graduated in decimals of feet - these are worthless to you.

We're still recommending Gougeon's west system epoxy as one of the most economical and convenient adhesives. The tests I am running with this

epoxy are most encouraging. An added advantage is its low toxicity - it doesn't effect the skin as much as most others. Be sure to add the 401 short fibers to increase viscosity to fill gaps greater than 1/32". The following order will go a long way and the mixer pumps save a lot of time weighing out each batch:

105 Resin	1 gal	$19.35
206 Hardener	1 qt	5.00
401 Shortfibers	1 lb	1.90
Mini pumps	1 set	2.75
Applicators	3 doz	3.00

Order from Gougeon Brothers, 706 Martin St., Bay City, Mi. 48706.

Jesse Wright S/N 91, is now manufacturing a kit of parts for the canard and elevators. The kit includes the following parts - routed to final shape and tapered where required: C-6, ER, ER1, E4, E6, C11, E5, CR1, CR and CRT1 - a total of 75 parts in all. I have inspected the kit and found it to be of excellent quality, using birch plywood. The kit does not include the spruce spars - those are in the spruce kit already available from Aircraft Spruce & Specialties, Fullerton, Ca. 92632. With these kits available, the homebuilder has only to assemble completed pieces, with little fitting or shaping required.

Do not order the canard kit from RAF. Contact Jesse Wright directly at 7221 S. Colorado Ct., Littleton, Co. 80122 (303) 711-5140. His price is $116.00, which includes all packaging and shipping, anywhere within U.S.A. or Canada.

Jesse will also have a complete kit of manufactured (routed parts to final shape) bulkheads available by November 15th. Contact him after that date for price and availability. We have not been satisfied with the service provided by the vendor of the drawn bulkhead kit now shown in the RAF catalog. Once the routed parts are available from Mr. Wright and have been approved by us, we will discontinue the drawn bulkhead kit. The routed bulkheads will save the homebuilder a considerable amount of work and guarantee him accurate, splinter-free edges. Mr. Wright plans to offer routed inboard wing ribs by mid December.

Good news for those who have asked us to make MG14 maingear legs available, George Evans, 4102 Twining, Riverside, Ca. 92509 has already made three shipsets for local VariViggen builders. They are of first-rate quality, welded of 4130 steel, heat treated, cadmium plated, and baked. The lower tube is honed for a perfect fit on the MG30 trunions. All tabs are welded in place and the uplock bolt hole is drilled/ tapped (see plans page 48). We are working with Mr. Evans on this item, but will not handle this in the RAF catalog; call (714-683-3963) or write Mr. Evans directly to order. He will also make available the MG32 trailing arm aluminum bars and the welded steel NG25/NG26/NG24/NG23/NG27 assembly.

VariViggen angle-of-attack system, fully assembled with or without meter, all components assembled to back of meter on printed circuit board - write Allen Vaughn (S/N 348), 1915 Florida St., Huntington Beach, Ca. 92648, or call (714)-536-8122, for price and availability.

THE CANARD PUSHER No. 7 JAN 76

NEWS OF THE VARIVIGGEN AND VARIEZE PROGRAMS
(very vig-in) (very easy)

RUTAN AIRCRAFT FACTORY
PUBLISHED QUARTERLY BY Burt & Carolyn Rutan
JAN, APL, JLY, OCT Bldg. 13, Mojave Airport
P. O. Box 656, Mojave, Ca. 93501

NEWSLETTER SUBSCRIPTION - $4.75/year
OVERSEAS SUBSCRIPTION - $6.25/year
BACK ISSUES - $1.00 each

RAF ACTIVITY since the October newsletter has been primarily the construction of the VariEze homebuilt prototype. This aircraft (N4EZ) is the Continental-powered aircraft that we are basing the plans on. See "Canard Pusher" number 6 for a complete description of the differences between the two prototypes. Construction of N4EZ was started on 15 October 1976. It is now (14 January 1976) being primered and finished. Yet to be completed are the cowling, instrument installation and hooking up the engine controls. It should be flying by the first week in February. Assuming that all flight tests go as expected, including spin tests and dive tests to 240 kt, and no large delays are encountered, we expect to have the plans and construction manuals on the market in April or May. Most likely, our April "Canard Pusher" will be the first announcement of plans availability.

VariEze static load tests conducted recently include the canard, winglet attach, elevon brackets, monocoque wing section, and several component tests. All results confirm the high safety factors previously claimed. We plan to static test an entire wing and attachment as soon as we can find something strong enough to mount it on!

Both the VariViggen and VariEze have been flying extensively over the last few months. N7EZ now has 220 hours; N27VV, about 570. Pilots checked out for solo in the VariEze include Peter Garrison, Tom Jewett, Peter Lert, George Mead, Jerry Slocum, Tom Poberezny, Dick and Burt Rutan. Approximately 75 people have been given backseat rides. Both the VariViggen and VariEze have been relatively maintenance-free over the last several months.

Since November, we have been giving weekly demos of our aircraft. Every Saturday from noon to 2 P.M. we roll the airplanes out of the hangar, discuss their features, give flight demos and rides in the VariViggen and VariEze. The demos start in our building - 100 yd southeast of the tower building on Mojave airport. We plan to continue giving these demos at least until the VariEze is on the market (April or May 1976). Until then, do not expect to see the VariEze at any other time of the week. Showing it on an individual basis has taken a large part of our time and has delayed the program. After it is on the market, come by at any time!

PHOTOGRAPHS OF VARIEZE, VARIVIGGEN AND VARIEZE CANARD OMITTED

We still have not seen any VariViggen projects appear in the "Sport Aviation" "What Our Members Are Building" page. Come on guys - send Jack Cox a photo and description of your project.

THE VARIVIGGEN OWNER'S MANUAL has been finished at last! It will be available for mailing in mid February. The owner's manual is a complete operational handbook for the plans built VariViggen including normal and emergency procedures, loading graphs, operations checklists, complete performance information for standard and SP wings, 150 and 180 hp. Also included are an expanded flight test section, maintenance checklists, record keeping section and much previously unpublished operational info. The manual is in a handy 5-in by 8-in size so that it will fit in the cockpit map pocket. The owner's manual will cost $6.00 including first class postage (within U.S.A.). This manual is a must for those close to first flight.

NEW VOR AND COM ANTENNAS AVAILABLE
We have been working with a group of electronic wizards on the development of a set of antennas for the VariEze and the results have been excellent. These units are 'zero drag,' immersed-type, antennas, specifically designed for composite or wooden aircraft. The performance of these units is equal to the very expensive broad band antennas. While designed primarily for the VariEze, these antennas are excellent for the Viggen as well.

We've received a number of comments on the VariViggen plans VOR antenna, most indicating that we don't show the 'optimum' antenna. This is true, but don't rip your canard apart if it's already installed. The plans antenna works well, but if you want the best possible antenna, there are other ways to go. Frank Stites of Stites Engineering Company, Wayland, Mass. has been kind enough to run a series of tests on antenna efficiency for us. He found that the antenna shown in the VariViggen plans received between 65 and 70 percent of the available signal. Extending the plans antenna arms by 2.45 inches (14.15 to 16.6) improves its reception to between 78 and 85 percent of the available signal. Our new antenna receives between 83 and 92 percent of the signal. There are antenna designs which will capture about 98% of the signal, but they don't fit into our aircraft very well. For those of you who are radio buffs, the VSWR ratios of these antennas are plans antenna (14.15 long) VSWR 3.2 to 4.2, plans antenna extended to 16.6-in length VSWR 2.2 to 2.8, H.C. 100 (new) VSWR 2.5 to 1.7.

The new antennas are available now directly from the manufacturer (not RAF). You canard pushers (RAF customers) will get a $10 price break on each of the NAV and COM antennas from normal retail prices. These antennas require no balun (it's internal). You guys who just can't wait to have a VariEze part in your garage, can get these antennas early and you Viggen builders will find them very good antennas (see installation sketch below). Order directly from H.C. Communications, P.O. Bx 2047, Canoga Park, Ca. 91306. The prices are HC100 (NAV) $28.50 (normally $38.50), HC200 (COM) $26.50 (normally $36.50). All that you need is a B.N.C. connector on the end of your antenna lead.

California residents don't forget to add 6% for tax. H.C. Communications promises delivery within 14 days of receipt of your order. **SKETCH OF HC COM ANTENNA INSTALLATION IN VARIVIGGEN OMITTED**

Should you have questions which you want answered directly, please send a self-addressed, stamped envelope for our reply.

VARIVIGGEN FIBERGLASS PARTS
RAF has been handling the cowling, tank cover, nose cone, plexiglass dome, and visor for a year now with excellent results. These parts have been manufactured by a firm next door here in Mojave, so delivery has been excellent. This firm has decided to discontinue manufacturing those parts for us, and we're changing to another very capable firm. Unfortunately, our new manufacturer isn't right next door and to avoid any delay in delivery, we will be sending you directly to them with parts orders. We feel that this arrangement will get parts to you the quickest and most economical way. We do have a few ship-sets left here at RAF for those of you on the west coast who want to stop by and pick them up. We aren't equipped to pack or mail these few remaining sets. Send your new orders to Monnett Experimental Aircraft, Inc., 410 Adams St., Elgin, Il. 60120. There may be initially a small delay until Monnett gets production going on our tooling, but this should only take several weeks. The parts involved are F23, F27, F25, F28 and V-COWL.

VARIEZE UPDATE
Each newsletter we try to answer the questions sent in the past three months which haven't been previously answered in newsletters or the information kit. If we miss your favorite this time, write and ask again.

Cost: We look at the airframe cost two ways, the cheapest and the easiest. The biggest single factor is the engine; you can scare up a zero-since-major A-65 Continental for $700 if you're a good scrounger ($1500 if you aren't) or spring for a new $4000 0-200 from Teledyne. If you buy only the raw materials, no machined parts, weld your own engine mount, etc., you can probably pump out an airframe with instruments for about $1300. On the other hand, if you buy all prefabricated parts that will be available, landing gear struts, machined nose gear parts, main gear axles, engine mount, stick assembly, wing attach fittings, fuel caps, nose gear retract motor, spinner, finished rudder pedals, canopy, cowling, etc., you can invest about $2400. There will be a lot of happy combinations in between these two extremes.

Engines: Don't buy one yet. We'll make our recommendations after we've flown N4EZ. We plan to solve all the installation problems with the small Continentals and then proceed to the VW installation. No, Fred, you can't use an 0-320 Lycoming in your Eze, not even an 0-235, because they're too heavy. The Eze is basically a 60 to 80-hp airplane; The 100-hp Continental 0-200 without starter and a light alternator is the maximum. We are using an 0-200 only so that we can qualify the heaviest and most powerful installation and insure its

safety. If the engine you're thinking of weighs more than 200 lb, forget it!

Heavy Pilots: 210 lb is considered top. You could fly with lead in the tail, but it's bad practice and severely compromises the design. The VariViggen is more tolerant of you heavies. You tall troops can relax, though; 6 ft, 4 in fits just fine. Anybody over 6 ft, 6 in will have to raise the canopy, which is a VariEze job if done during construction.

EAA: You guys who aren't members, should be. If you aren't a member yet, borrow your friend's January "Sport Aviation" and read the 10-page Eze article. It's a more comprehensive article than any of those previously published, particularly in regards to the structure.

Registration Numbers: The FAA assigns these, not RAF; contact your local GADO for the application procedure.

Record Flights: These take time and gobble money. We have delayed the coast-to-coast attempt until after plans are out.

Wives: Due to your dress making skills, your participation in VariEze construction can be much more than in conventional construction. In fact, you will probably be responsible for about 20% of the effort, cutting the glass cloth. Cloth cutting needs to be done on a clean table with a good pair of scissors. Your skill in this area is probably better than hubby's and we're sure he will appreciate the help.

Mods and Goodies: Don't ask about dual controls, inertial navigation systems, lighting, heaters, starters, inverted fuel systems, ad infinitum, until the basic airplane is finished, thoroughly tested, and you have plans and parts in your hot little hands. We will develop many of these, but only after the basic configuration is completed.

Foam: All foams (kit includes three types, five different densities) will be available in the correct odd ball type and sizes from our distributors, as soon as the plans are out.

Epoxy: Our education is improving all the time. The Shell epon epoxy that we had been using is late 1950's technology. We are working with some more modern materials that have better peel strength and will tolerate higher heat without softening. These advances make for a stronger airplane and allow a choice of colors where the older resins commanded a basically white airplane. We have a bunch of testing to do on this resin yet, before we release details, but if all goes well, you can have that chartreuse airplane after all.

In recent weeks, we've had the opportunity to discuss at length our structure with the advanced composite materials department of a major aerospace firm. These guys spend about three to four million dollars a year on composite research. We were very much pleased to find that these true experts in composite structures had only complementary comments for our approach. This group has also been very helpful in recommending primers for complete protection of the foam and resin from ultra violet radiation.

Misc. Performance: No, you can't hit the prop when you flare to land or rotate to take off.

Altitude performance is excellent; even a normally aspirated engine will take the airplane higher than the pilot's lungs can go without oxygen.

No, there isn't any pitch trim change with throttle. If you cycle the throttle from idle to full suddenly, all you get is acceleration with zero pitch or yaw.

* For a crew weight of 300 lbs. total. Fuel and range is reduced for heavier people

---

Cabin Noise: The cabin noise level in 7EZ is lower than most light airplanes; however we plan to improve this even more on 4EZ with the addition of a muffler.

Pusher Engines: As you engine experts know, the Continental 0-200 (100 hp), C85 and C90 engines have a special crankshaft for an FAA-approved pusher installation. These special cranks are rare and expensive. We don't believe that these special parts are necessary for the VariEze. The difference between the "pusher" 0-200 B and the tractor 0-200 A is a reinforced flange to take the high static thrust loads that you find in amphibian type or other slow aircraft. The 0-200, C85, C90, C75, A80, A75 and A65 crankshafts are almost identical (not interchangeable) and the A65 engine is approved as a pusher without modification. Because of the fixed-pitch prop, designed for 200-mph cruise, the

thrust loads on the 100-hp 0-200 A are lower than they are on the 65-hp A65 in a "normal" installation. It is possible that you might have to plug an oil passage in your crank case for improved lubrication. We are testing this on 4EZ and will include our findings and recommendations in the plans and later newsletters. **GRAPHS OMITTED**

Dealers: We've had a number of inquiries from individuals wanting to be "dealers" or "retailers" of plans, parts, etc. Our current situation is that we are under contract with several very reputable firms for the exclusive manufacturing and retailing of Eze materials and components. These contracts are in effect for two years as exclusive agreements. After this initial period, we will address expansion to a larger dealer network. In the meanwhile, we suggest that overseas customers wishing to save on import costs, make volume orders.

Building Skill: Many of you have expressed concern about the skill required to build the VariEze. If you can chew gum and walk a straight line simultaneously, you won't have any trouble at all. For those who have trouble with this, we will be holding seminars and demonstrations around the U.S. after the plans are out. Seriously, the skill required to make a good, safe structure is less than that required for sheet metal, wood, or welding.

Forget any experience you may have had with fiberglass using standard industrial weaves or boat cloth. The special weave cloth used on the VariEze requires only about one-half the time to lay up as you may be used to, and the low resin amount required to wet out the cloth results in a significant weight savings. The VariEze plans are much more than just drawings: they are a very detailed "education" and step-by-step construction procedure description. We even plan to tell you how many man-hours you should spend in each step. This allows the builder to compare his performance with a norm and will allow him to tell, at any time, how much work he has yet to do. Tools: We have also received many inquiries about the tools required to build the Eze. Most tools are of the common tool box variety: screw driver, wrenches, saws, hammers, etc. This is a short list of the special tools: hot wire saw (homemade using safety wire and an auto battery charger), moto tool dremel or weller home shop hand grinder, X-acto knife, epoxy ratio pumps or balance, tongue depressors, surform file, scissors and butcher knife. A band saw (wood and aluminum cutting), small sander and a drill press are nice but not required.

Starter: OK, you guys who insist on installing an electric starter, look at what you're doing to your airplane. First, you add a 16-lb starter to your engine, then add a 25-lb battery in the nose to balance and power it, then add six pounds of cable to connect the two (both ways - You can't ground to glass and foam). Presto, you've added 40 pounds of empty weight that does nothing except in the first five seconds of a flight. A small seven-lb battery gives you everything you need for avionics and lights. For the privilege of pushing a button once each flight, you have reduced your useful load carrying ability by 10%. Look at it this way, your starter equipped airplane will go 330 miles less with the same takeoff weight as my hand-propped model.

VARIVIGGEN PLANS CHANGES

Be sure to incorporate these revisions into your plans now.

Location PL - Plans
TR - Tech Report
NL - Previous Newsletters
CAT - Catalog

Category of Change
MEO - Minor error or omission
OPT - Optional improvement
DES - Desirous change; does not effect flight safety but should be incorporated to improve aircraft or correct a fault.
MAN - Mandatory change; must be incorporated as safety of flight is affected.

Category	Location	Change
MEO	PL pg 41, pg 57	RP1 sketch - Tube size 5/16x.035 not 5/16x.063 for AN4 bolt.
MEO	PL pg 40	Change AB belcrank rivets to -15 not -9 as shown.
MEO	PL pg 30	Aft end of OW2 sq. tube should be welded closed or filled with a phenolic block.
MEO	PL pg 15	C1 is under size to mate with CR. Either file CR5 down to match C1 or make C1 over size to match CR.
MEO	PL pg 47	16.7 dim should be 16.2 on MG14 detail.

SP WING PLANS

As we mentioned in newsletter six, the special performance wing plans are ready for mailing. The plans price of $39.50 (Calif. residents add $2.37 tax) includes plans and a very complete construction manual with instructions so detailed, that they may insult your ingenuity! The plans include full-size rib lofts, composite rudder, and winglets. The construction manual includes photos.

A number of builders have asked us if the composite structure of the SP wing can be used on the standard wing. We don't recommend anything for you that we haven't flown ourselves, but, we don't see any reason why the information in the SP plans, together with the lofts and information in chapters 3 and 10 of the standard plans couldn't be used to build a set of composite panels for the standard airplane. The composite wing would be a stronger wing than the metal wing. Since the ailerons on the standard wing are larger than the SP ailerons, the hinges for a composite standard wing should be 10 inches long instead of 6 inches long. The addition of winglets to the standard wing should also improve it's performance, more so, than the SP wing because of the lower aspect ratio.

Since we had the SP plans printed, we have developed an optional aileron (or rudder) hinge stiffener plate which replaces the plywood parts and screws with a sheet metal angle as shown in the sketch. This method makes the aileron (rudder) to wing (stab) fit up much easier. To install, remove a 1/8" gap of foam, 1-in deep adjacent to the skin, bend the .020 alum AA7 angle to fit flush along the foam face and

against the hinge. Hold in place while drilling holes through the skin, hinge, and AA7 for rivets. This can be done on both sides at once with the aileron in place on the wing. Use clecos to hold the hinges while drilling. Remove the hinge and AA7, fill the gap with flox and install the hinge (one side at a time with the hinge pin removed) using pop rivets. The glass skin on the vertical face should be applied now to give a wet bond with the flox used to mount the hinge. **SKETCHES OMITTED**

VARIVIGGEN BUILDING TIPS
Jim Cavis moved his MG9 pulleys outboard 0.15" as suggested in newsletter 4 to use the shorter MG4 beams supplied by RAF. With the new location for the pulley, Jim found it to be advisable to bend the uplock belcrank inboard and put the bolt on the outside (see photo). The photo also shows the fairlead pulley on the aileron cable to provide additional clearance with the gear parts. If you have the short MG4 beams, you may find that its easier to weld a strip of steel on the end to extend them to the plans dimension rather than move MG9.

Jim also cut a 2-1/4" dia hole in F152 above the MGMA to aid in the installation of the MG42 spool and so he can see the MG42 spool in action. He reports the entire gear is now complete and operation is satisfactory.

It is possible to get the cables forward of the spar instead of in the close quarters behind F152. I did this on N27VV with pulleys as shown in the sketch. You can use this method if you wish to have better access to the cables and turnbuckles. I don't think the extra complexity of pulleys and brackets is worth it though.

Jim reports it took six people and a case of beer to turn his Viggen over after skinning the bottom: sounds like an overkill to me!

SKETCH OMITTED

Orv Winfield reports that auto parts stores carry what they call a "tank valve" - a tire valve with metal 1/8" pipe thread. This should work fine on the nosegear strut. He paid 56 cents for his.

Several builders have reported difficulty with warping when welding NG15 to NG13. This can be avoided by welding a small ring of .063 steel to the tube and bolting on NG15 with six #8-32 screws (see sketch). **SKETCH OMITTED**

When cutting WR25 it is not necessary to cut the notches for Spar H and I. Spar H and I do not have to pass through WR25; adequate support is provided by WR24.9 ribs. Thus, fitting the notches is not necessary.

Landing gear motor assemblies - The accompanying photos show the assembly used by Pastor Bruce Jenkins. He hinged the motor (a Ford part number DOAZ-5723395-A) from the opposite side and supported it with a 'u' channel fit to the motor housing. It mounts firmly over the F30 fitting on the left side. The large plate is .125 alum. The large

gear is a Boston ND64. He used a similar setup on the nose gear with a Boston ND30. These gears mesh directly with the Ford unit.

Ken Guscott went one step further and built a rigid box to house the large gear providing bearing support on both sides. He also uses a relatively complex system to provide lateral disengagement for emergency extension. While a bit on the complex and heavy side, his system is well engineered and should provide excellent operation. He has made up a full-size drawing of the system and will distribute it to other builders at a nominal cost for reproduction. He also has a drawing for his homebuilt nose gear designed around a surplus shock strut. His address: 12 Richards Road, Lynnfield, Mass. 01940.

VariViggen Hydraulic Brake Line Routing:
As shown on plans page 41, flexible line runs from the master cylinders to a bulkhead fitting through F31. Half hard (5052-1/2H) 1/4 O.D. aluminum line is run from this fitting inside the nosegear box through F32 aft along the side (inside) the tunnel. The aluminum line is routed aft to Spar B then outboard along the front face of Spar B to another bulkhead fitting mounted on WR46.

Route the aluminum line through Spar B at B.L.45 and W.L.3. From the WR46 fitting a flexible line is run aft about 6" then looped forward and down the shock strut to the brake. This leaves a loop of flex line outboard of the gear door cutout. Check for chafing of the brake lines during gear retraction. **SKETCH OMITTED**

Asbestos fiber that we at one time recommended as an epoxy thickener has been identified as a possible health hazard if you breathe the dust. We no longer use it at RAF and don't recommend that you do either. As a non-toxic substitute, we recommend flocked cotton fiber (Gougeon Brothers 403 fiber).

The following sketch shows the battery location first used in N27VV. Note that the long dimension is positioned fore-aft to give room for the nose gear in the retracted position. I later moved the battery to between F70 and F91 after adding other equipment and finding that I didn't need the nose weight. Each builder should mount his battery after the first weighing to determine the optimum position for his aircraft. **SKETCH OMITTED**

VariViggen builders now total 440. Those of you with a VariViggen aircraft serial number will find enclosed with this newsletter, an update to the builders list.

f you can't find the 1/2" sq alum tube for the canopy, substitute 1/2x.049 2024 T3 or 6061 T6 round tube and use larger corner gussets and three extra rivets into the tube at the corners.

SHOPPING
We've heard reports that some suppliers have charged nearly twice the going or promised price on items which were ordered. We suggest that

you get a price quote and a promised delivery before ordering anything from an unfamiliar source.

Ken Brock Mfg., 11852 Western Ave., Stanton, Ca. 90680 is manufacturing the light weight fuel cap assembly for the SP wings and they are available now. Ken has a beautiful illustrated catalog for $1.00, unfortunately the fuel caps were too late to be included.

Bill Campbell, S/N 325, Bx 253, Phelan, Ca. 92371, phone 714 249-6218, is manufacturing the following parts for VariViggen builders: C8, C9, C12, C14, C16, C18, C19, C21, C15, EC3, EC5, E6, F29, F30, WF45, WA1, R11, AA3, SA4, SA5, SA8, SA9, SP5, PA5, PB2, PD2, AB2, AB3, AB4, AB8, AB12, AM2, RB2, RB3, PF2, PC2, EM2, NG11, NG16, NG17, NG19, NG21, MG8, MG9, MG10, MG20, MG22, MG24, MG29, and a 30-gallon fuel tank that fits in to the standard space. For prices and availability, send a stamped self-addressed envelope to Bill. Having these completed parts can really speed up your construction project.

Flight Test Assistance - We are planning to provide a pre-first flight inspection and initial flight test assistance service for our builders. This would involve us visiting your flight test area, giving your aircraft a very complete inspection and rigging check, prior to first flight and either flying your first flight or checking you out in N27VV to improve your proficiency for your first flight. Providing flight test assistance in expanding the flight envelope of your airplane would also be very beneficial in assuring flight safety. This service will only be provided to those who are building the airplane without major modifications from the plans, and flight envelope expansion on your aircraft will be limited to the envelope shown in the aircraft operating limitations, plans page 3. We will provide this service to the first three builders who complete their aircraft, free of charge except for transportation costs.

National Scientific Co., P.O. Box 901, Melbourne, Fl. 32901 is offering a kit for a capacitance fuel gauging system that promises to be lighter and more accurate than the float type gauge. The FG15 kit price is $43.40.

Pastor Bruce Jenkins, S/N 177, Rt 1, Eagle, Mi. 48822 has two Continental 0-200 B engines with accessories, currently undergoing chrome major, for sale. These engines will be available for delivery in mid March. A certified check or money order for $2150 will hold one for you.

Australian and New Zealand builders, who need a certified epoxy, contact Consolidated Chemicals LTD, New Zealand for information on their product "epiglue."

Gougeon Brothers, 706 Martin St., Bay City, Mi. 48706 has a hand cream for epoxy workers that enables you to clean up with soap and water only. You can order this barrier skin cream (ply no. 9) for $2.60 a one-lb jar.

We've heard from several builders that G & J Aircraft and Industrial Metals, 1115 S. Sultana, Ontario, Ca. 91761 has good prices on hardware and metals.

George Evans, 4102 Twining, Riverside, Ca. 92509 is pumping out welded assemblies for VariViggen builders. George has added the NG25/26/24/23/27 assembly with an adjustable NG27 to his stock and they are available now. George also has MG14's, MG32's, and EM1 weldments. You guys who have had trouble finding 1-1/4-in square tubing just write to George; he has 1000 ft of it fresh from the mill. George has also become a distributor for the Scott tailwheel ass'y and he's offering them below retail for VariViggen builders ($186.). All of George's products that we've seen, have been of excellent quality and workmanship.

Vernon Williams, S/N 189, 4 Southmont Cir., Little Rock, Ark. 72209, reports that he still has a fuel tank for sale of the type he had at Oshkosh.

Those of you that are still having trouble locating materials, should get an Aircraft Spruce & Specialty catalog. This outfit provides excellent service and has a very complete "in stock" line of everything from plywood to hardware and instruments. One builder noted that their precut VariViggen spruce kit (certified spruce) was cheaper than buying spruce from his local lumber yard. Their address is Bx 424, Fullerton, Ca. 92632. Catalog cost of $2.00 is refundable on first order.

Jesse Wright, S/N 91, is in production with his canard kit, having delivered the first half-dozen or so. Jesse is also manufacturing a bulkhead kit. If you're interested, write directly to Jesse Wright, 7221 S. Colorado Ct., Littleton, Co. 80122. His canard kit is priced at $116 including packing and shipping (in the U.S.A.). We listed Jesse's phone number incorrectly in newsletter 6; it is 303 771-5140, not 711-5140 as shown.

RAF is no longer handling the VariViggen bulkhead and rib kits. We do have a couple of sets here that we can sell at a discount to anyone who would like to pick them up at Mojave - we're no longer equipped to ship them. If you still want the bulkheads and ribs drawn on plywood, (not routed out like Jesse Wright's kit) you can order them from Aircraft Materials Co., 850 E. San Carlos Ave., San Carlos, Ca. 94070. Write them for price.

N4EZ with 3rd generation inlet airscoop. Scoop has since been made smaller.

Hand propping is VariEze and requires no chocks or tiedowns. Rubber bumper on nose is better than a chock.

Ground handling is VariEze.

Panel on prototype - see text for other layouts. Note the stick and throttle quadrant - these will be offered as "ready to bolt in" parts.

RAF ACTIVITY since our January newsletter (no. 7) has been hot and heavy. We've spent considerable time refining our composite construction methods (VariEasier), conducting structural tests, and flight testing the Continental-powered VariEze, N4EZ. In addition to supporting our VariViggen builders and writing the Viggen owners manual, we've been burning the midnight oil releasing VariEze manufactured items and materials for production and working on the Eze plans. Regrettably, we've also spent a full third of our time answering letters and telephone calls from people requesting a personal Eze program update. We know that you folks are excited about the program and we really appreciate the interest, but please save your dime so that we can get the job done! Once we have the plans done, we'll gladly answer all of your questions. Until that time, we must ask you to leave us alone so that we can work. Preparation of the manufacturing manual for the Eze homebuilder is a very big job. It can be completed by late May if we can reduce the interruptions. You are welcome to visit us from noon to 2 P.M. any Saturday for our weekly demo, but don't come during the rest of the week. We cannot show you the airplanes during the week.

In the last few weeks during the Saturday afternoon demos, we have been giving composite construction demonstrations. We will continue these construction demos to give our Saturday afternoon visitors a first-hand

look at the method used in VariEze construction. Flight demonstrations will not always be given on the Saturday demos since we plan to take the VariEze and VariViggen to several flyins this summer, including Corona, Watsonville, and Oshkosh. We will plan to have a construction demo set up though for any Saturday visitors.

VARIEZE DEVELOPMENT FLIGHT TESTS - The prototype for the homebuilt program (N4EZ) made its first flight on March 15. As of this writing (15 April) it has logged 35 flight hours. The test program has progressed very well to date, the aircraft being in flight-ready status essentially all the time. There have been a number of changes required as a result of the tests. These are all covered in the following:

Flying Qualities - The aircraft initially had poor harmony between the pitch and roll forces - pitch too light and roll too heavy. We made two gearing changes in the control system (different length arms) to tailor the forces to what is now considered optimum. Pitch forces are now about three to four lb per g, which is just about right for a side stick control. Roll rate without rudder is slower than the average light plane, but when coordinated with rudder, the roll rate is more than adequate at all speeds.

Hands-off stability is better than the average light plane. Trimmed up, it will hold altitude and heading, even in turbulence, without touching the controls. I recently flew a 3-1/2 hour flight, while touching the controls only for about 10 minutes - take off and landing. Turns were made by leaning in the cockpit and the aircraft held altitude between 10,500 and 11,000 feet for three hours.

Dynamic damping is dead beat in pitch and roll and one-overshoot in yaw at all speeds. The phugoid damps in one cycle, which is quite good for a clean, fast aircraft. There is no pitch or yaw trim change due to power changes. There is a roll trim change, and we have verified this to be due to direct engine torque, not aerodynamic effects. It was not significant on the VW powered aircraft, since the torque is low on the 60-hp, high rpm engine. The difference of roll trim from full power climb to idle descent is enough to be a nuisance, so we added roll trim to the aircraft. This is a small tab (1 1/2"x10") at the wing tip, actuated by a model airplane servo. This "separate surface" trim is preferable to elevon trim since it does not effect elevon authority and is a handy inflight adjustment for any wing twist tolerances.

Stalls in the VariEze can best be described as 'boring.' The design of the two wings are such that the aircraft is self-limiting to about 14-deg angle of attack. The technical reasons for this are beyond the scope of this discussion, but the result to the pilot is as shown in the accompanying graph. A normal relationship of elevator position required to hold airspeed (or CL) exists up to about 12 degrees angle of attack, which corresponds to about 52 knots or CL=1.5. This is also about the angle of attack of maximum CL of the canard surface. As the stick is brought further aft from the 52-knot position, the pilot notes four things: 1. It takes a lot more stick motion to get just a little slower speed and full aft stick is reached in a nice stable flight condition at 48 knots (CL=1.66). 2. There is an occasional mild pitch bucking motion below 50 knots, but no g-break, yaw, nor roll motions. 3. Power required to fly level is not greatly increased (I was climbing at 14,000 ft, 48 kt, and 1/3 throttle!). 4. Roll control with the

ailerons begins to degrade below 52 knots, however the airplane is VariEze to fly with the rudders at any speed, including full aft stick (48 kt). At 48 kt the airplane cannot be rolled with the elevons (somewhat like a Cub near stall). **GRAPHS OMITTED**

Tuft tests show excellent attached flow on the vertical fins at all speeds, and some trailing edge local turbulence near the wing tips and canard below 50 knots.

Accelerated stalls are similar. We don't know yet if the VariEze will spin, but we do know an even more important fact: it is much less susceptible to inadvertent spins than the common light plane.

The independent rudders move a total of about 50 degrees which makes them effective as speed brakes. If you're high on final approach, the rudders can be extended to add about 200-ft-per- minute rate of sink.

The overall flying qualities can best be described as "comfortable." Certainly not aerobatic, due to the low roll rate, but excellent for its primary mission: travel from point A to point B with little fuel used, and at a high cruise speed.

Performance - The following performance data are from flight tests with N4EZ. They are based on a plans-built aircraft with wheel pants. All data are for a fixed-pitch cruise prop except for the 65-hp engine - we are recommending a climb prop for the 65-hp installation to improve take-off performance, at a 10-kt cruise penalty - this is why the 65-hp take-off and climb performance is the same as the 75-hp data. **GRAPH OMITTED**

VARIEZE PERFORMANCE GRAPHS OMITTED

MISC VARIEZE DEVELOPMENT ITEMS

Cooling - N4EZ overheated on its first flight. The original cowl inlet was designed more for low cost production than for pressure recovery. We instrumented the high and low pressure plenums and built a large, ugly scoop for the bottom. This gave more than adequate cooling, but resulted in a five-kt drag penalty. We then built the 65 square inch inlet shown on the pictures in this newsletter. It gave a 3-kt speed increase and still cooled as well. Since the pictures were taken we have reduced the inlet to about 42 square inches and have found this to be optimum for the 100-hp engine. Cruise temperatures are oil=170 degrees F, cylinder head=360 degrees F, both well in the green. Concerning the inlet, different inlet areas will be required for the different hp engines. To keep the cowling price low, we plan to offer the basic shape and have the homebuilder build up a foam/glass lip as shown, to match his engine size. We now also know that the outlet area is too large and that some more performance can be gained by a better cowl/spinner fit. However, we feel that it is much more important to get the plans our first, rather than spending the next two weeks going after four more knots speed. Therefore, we are not going to change the outlet until after the plans are out. This means that the cowlings will not be available until about two months after the plans are out.

This will assure you of an optimum cowl, without us delaying the plans. **SKETCHES OMITTED**

Engine Installation - All aspects of the Continental engine installation have worked out excellent. The simple homebuilt carb heat box is mounted on the airframe, free from engine vibration. It mounts on an automotive-type air filter which is much more effective than the average aircraft filter. Induction system losses and mixture distribution is equal to the best systems we've seen. The carb heat muff is a very simple two-piece, easily built part that provides a 90 degrees F temperature rise using only the left exhaust system. This leaves the right side available for a simple cabin heat system. However, as long as the aircraft is flown day-VFR, a heater is not required - the canopy traps radiant heat that is held by the foam-insulated fuselage structure. We are using a low cost exhaust system with a homemade glass-pack muffler. The lightweight muffler removes most of the engine noise, the remaining noise being mostly from the propeller. The VariEze cockpit noise level at cruise is about like a late model Cessna, allowing conversation at a normal voice level. Absolutely no indication of any problem has been seen with the pusher thrust bearing, using the tractor engine (see newsletter 7). Crank end play shows no wear and case temperatures are normal.

Pitch Trim - Pitch trim initially was done by a handle that operated a spring, connected to the stick. After we changed the pitch gearing, the trim loads were increased such that it was difficult to precisely trim the aircraft. We then changed the handle to a 1.5-diameter knob that the pilot turns for pitch trim. The result is a precise trim system that has fewer parts and is easier to build. The obsolete handle is in the panel photo in this newsletter (pg 1).

Nose Gear Retraction - An important design feature of the VariEze is its retractable nose gear with capability powerful enough to raise and lower the nose on the ground with the pilot and passenger aboard. This allows the aircraft to be parked in a very stable attitude on the ground, "chocked" for starting the engine and allowing easy pilot entry and exit without a ladder. Development of this feature, however, has been a very difficult and frustrating experience. N7EZ had a simple-concept system as shown in the sketch, using a recirculating-ball screw assembly to provide low friction. The system allowed the pilot to crank himself and a passenger up and down, (33 turns) but if he let go of the handle in the process, it would spin wildly around and let the nose down hard. **SKETCHES OMITTED**

I didn't like the system, primarily because the ball screw assembly was expensive. We used the same concept on N4EZ, but replaced the ball screw with a lower cost Acme screw threaded rod, hoping that the extra friction would solve the spin problem. We found that even with a 45-turn gearing, the system would bind up under load, requiring a heavy two-handed effort to crank the nose up with the pilot in. We installed an electric auto window motor which works okay, but takes 35 seconds for gear retraction, requires an electric system in the airplane, and costs over $50 just for the motor. This, of course, was not the most satisfactory approach. Sometimes it is best to back off and look at

the forest instead of the trees - I did, and realized the basic problem was that the hand is very inefficient in turning a small crank with the arm in line with its axis of rotation. The most efficient manual capability is an aft pull of the arm, using the biceps muscle. We found a low cost jack-type mechanism that can be installed and easily rigged to allow gear extension/retraction with 10 pulls of a D-ring handle mounted on the instrument panel. This should allow a much faster, easier to build, much lower cost gear transit system. We are now installing this system on the VW-powered prototype, N7EZ, for testing. Incorporating this change will, of course, cause some delay but that's what our type of business is about. If we knew exactly how everything would work, we wouldn't even have to do flight testing!

Static Test Wing - Our static load test wing is completed and will undergo proof-load tests soon. After proof load testing the wing will be given to another organization for fatigue testing. The glass layups on this wing were done by an aviation writer who had no previous fiberglass experience. He was curious if he could do the work and we wanted a first-hand look at how well a beginner followed our wing plans. His work looked fine to us and he was pleased with the ease of construction.

VARIEZE WORK AREA AND TOOLS
Shop Size - Of course, a nice roomy 20'x30' work shop is ideal, but a VariEze can be built in an area as small as a single-car garage (10'x18'). The new epoxies used are less toxic and have less odor than contemporary ones, but we still strongly recommend a well ventilated work area. If you are considering a stuffy basement, rig up a small ventilation fan to move out fumes during the glass layups. The temperature of the shop must be maintained between 60 degrees and 90 degrees F during the glass work, 75 +-5 degrees being ideal.

Table to Jig Wings and Canard - This is any relatively flat surface at least 10 ft long x 2 ft wide. Any larger than 4 ft by 12 ft will just get in the way. The sketch shows the one we built and it works fine. The box design makes it stiff in torsion. Don't get carried away with surface finish: you will be gluing jig blocks to it with Bondo and chiseling them off several times. Set it up with the top 34 to 39 inches above the floor. **SKETCH OMITTED**

Tools - There are certain tools required to build a VariEze. Three lists are provided here. The first one is the absolute minimum required, sacrificing efficiency; the second is a recommended list for a good compromise of cost and work efficiency; the third is a list for the "Cadillac" of shops, where ease of construction is more important than money. Don't call us now asking how to find the odd-ball items. These will be available where you buy VariEze raw materials.

1. Basic Minimum: Common household butcher knife, coping saw, pliers, 1/4' drive socket set, set of small open end wrenches, 1" putty knife, hacksaw, screwdrivers, box of single-edge razor blades, 24" carpenters level, carpenters square, 3-ft straight-edge, 12-ft steel tape, 1/4" drill, roll of gray duct tape, box of 1" and 2" paint brushes, several 6" plastic squeegees, scissors, wire brush, pop rivet puller.

2. Recommended (in addition to #1): Dremel-type miniature high speed hand grinder (set no. 261 is okay), 1" and 1/2" chisels, small set of

X-acto knives and razor saw, stipple roller, 100-deg. countersink, 6" steel ruler, 6" to 9" disc-type hand sander, saber saw, Stanley surform plane, square and half-round files, several 6" C-clamps, vacuum cleaner.

3. First class shop (in addition to #2): Drill press, bench mounted belt sander, 18-inch band saw, epoxy ratio pump, 90 degrees drill adapter, air compressor with blow nozzle.

4. Items used only occasionally and can be borrowed: Nicopress sleeve swage tool, 12-volt battery charger for hot wire cutter, one dozen 1/8" clecos.

VARIEZE MATERIALS - It still looks like the materials cost (less engine) for the Eze will be about $1300 for those willing to build everything. If you buy all prefab parts that will be available (landing gear, axles, engine mount, rudder pedals, stick assembly, elevon pivots, wing attach fittings, fuel caps, canopy, cowling, etc.) the cost, including all raw materials and instruments, should be about $2600. You can pick any number between these values, depending on how much you want to build.

Our distributors are already stocking most of the items. The manufacturers have already built several hundred of many of the prefab parts. We expect that all raw materials, tools and prefab parts (except cowling) will be available in quantity when we release plans. We will identify all distributors in newsletter 9 and in the plans.

VARIEZE PLANS - We really don't like to call them plans - a better description would be manufacturing manual. They include a 30-page educational section that gives you a very complete introduction to the materials and detailed methods used to build the VariEze. The plans themselves are not just engineering drawings, but a very complete step-by-step manual showing each operation required. If you're curious about the format, find one of your wife's Simplicity dress patterns and look at the instruction sheet that comes with the pattern. We have found that this format of words, photos, and sketches, to supplement the normal drawings, is a very effective approach. Each major job is detailed and in each step you are told how many man-hours should be required.

The basic plans will consist of about 150, 11"x17" sheets, plus some larger full-size drawings. The plans will be offered in several sections:

Section I - Composite structures education, construction manual and drawings on entire aircraft except engine installation and optional electric/avionics systems.

Section IIA - Continental Engine installation. Complete instructions and drawings for 65 to 100-hp Continental engine installation: baffling, fuel system, mounting, exhaust system, carb heat system, engine instrumentation, cowling installation, propeller and spinner and engine operating specifications.

Section IIB - Same as IIA except for aircraft conversion of the Volkswagen engine.

Section IIC - Same as IIA except for alternate engine.

Section III - Electrical/avionics: drawings, specifications and installation instructions for optional electrical system, night lighting systems, avionics and antennas, and instrumentation associated with electrical system.

Section IV - Owners manual: flight and maintenance manual for the VariEze similar to the VariViggen owners manual. Includes normal and emergency procedures, loading graphs, operation checklists, detailed flying qualifies descriptions, performance charts, maiden flight test procedures, pilot checkout procedures, maintenance checklists and a record keeping section.

So, if you want to build a basic VFR VariEze with a Continental A-75, and without electrical system, you will need sections I and IIA and then section IV before your aircraft is ready to fly. If you insist on loading your aircraft up with avionics and lighting, you can get section III. Section IIB should be available as soon as the VW engine installation is completely proven out, possibly within three months after section I is released. If you want to use a VW conversion, you can get section I, start building your aircraft and then get section IIB when its ready. Section IIC is being pursued now, because it is obvious that the supply of used 4-cylinder Continental engines will be quite short within about two years. As these engines start getting scarce it will be important to have an alternate engine to keep the VariEze program alive. There are actually four different engines now being considered, all in the 80 to 90 hp range, light weight, and relatively low cost. These are being developed by other organizations; RAF does not plan to undertake engine development. But, don't get excited about getting these real soon. Aircraft engine development is a very big and expensive job and, while I have every hope of getting an alternate engine soon, I think it will be about a year until one of these "new" engines proves adequate. Do not contact us to consider any engine you may have in mind, unless it has at least 800 hours of reliable flying time.

Now for the big question - when will the plans be ready?? They are now more than half written and laid out. We have been, and will be, working days, evenings and weekends on the plans. We think they will be done in late May. The new nose gear extension system may delay this, but we don't think by much. Due to our policy of not selling anything we don't have, we cannot let you order plans at this time. We do have a plan to notify all subscribers of "The Canard Pusher" when they are available: as soon as we take sections I and IIA of the VariEze plans to the printers for printing and binding, we will immediately write newsletter 9, in it giving all information for ordering the plans. Thus, "Canard Pusher" no. 9 may be published in early June, giving you firsthand notice of plans availability. So, please do not call or write asking when they will be available; we will notify you as they go to the printers.

Initially, we do not plan a large promotional campaign to advertise VariEze plans. We want to wait until a few months after the plans are on the market to be sure the distributors are keeping up with demand on the raw materials and prefab parts. Our announcement of plans availability in newsletter 9 and in "Sport Aviation" is our only planned initial promotion.

CONSTRUCTION SEMINARS/AIRSHOWS - Due to the uncertainty of exactly when the plans will be finished, we cannot schedule specific seminars now. Newsletter 9 will announce any seminars we can schedule by then. We do plan a daily construction demonstration in the synthetics workshop at the Oshkosh, Wisconsin EAA convention. VariEze forums at Oshkosh this year have been scheduled for Monday, August 2 and Thursday, August 5. A VariViggen forum will be Wednesday, August 4. We plan to have the VariEze and VariViggen at the Corona, Ca. (1 & 2 May) and Watsonville, Ca. (29 & 30 May) flyins.

VARIEZE QUESTIONS

ATC Radar - I'm not sure why, but the VariEze is picked up on Air Traffic Control's radar similar to light planes built from metal.

Ultra Violet Protection - While glass needs no protection, the epoxy and foams do require an UV barrier to protect against long term degradation in sunlight. A UV barrier is sprayed on before final color paint. All finishing materials required and methods to get that "competition sailplane" contoured finish we put on our airplanes, will be published in a booklet "Finishing the Composite Homebuilt Airplane." This booklet will be available this summer - it is applicable to any aircraft with an epoxy/fabric exterior.

Very Low Temperatures - Several people have asked how the structure withstands the low ambient temperatures common to the North. I think this concern stems from thermal stress failures that have occurred on another homebuilt that has a relatively weak surface skin and a highly insulated main spar. The VariEze structure bears no resemblance to that structure - spar caps and skin being at the surface minimizes thermal stress. The glass/epoxy matrix actually has improved physical properties at low temperatures. These same materials are used in structural areas of military aircraft whose high altitude envelopes requires them to be qualified to below minus 70 deg. F.

Instrument Panel Room - The accompanying sketch shows three different instrument panel layouts. The first one is what we recommend for the VariEze - a low cost, lightweight panel for high performance day VFR utility. A com radio is needed to get any cross-country utility now days, but the rest is bare bones, giving more leg room. The other two layouts show the capability to stuff different type equipment in, for those who like to gaze at clocks. **SKETCHES OF INSTRUMENT PANEL LAYOUTS OMITTED**

Closure Inspections - When does FAA inspect the structure? The glass is applied over a solid foam core - thus there is nothing to inspect before skinning. All joints and all structure is inspectable from the

outside, and must be done after the structure is built but before it is painted. You will be given specific inspection criteria in the plans. In addition, since not every FAA inspector is familiar with composite structures, we plan to supply recommended inspection criteria to all FAA regional offices and to the foreign agencies.

Suitcase Size: Two suitcases, size as in sketch, fit into the back seat area on the sides up against the front seat. When empty, they take up little room. When full, they take up some of the lateral (sideways) leg room of the back seater. These suitcases will be available in completed form from VariEze distributors. In addition the Eze has two map cases (under front seat thigh support and in roll-over structure) and baggage areas behind the rear seat and in the center section spar. **SKETCHES OMITTED**

Prop Sizes - We have tested four different propellers, including a three-blade. We plan to test at least two more before we finalize the prop specification.

80-Octane Gas Availability - Continental engines offer a conversion to all the 65 to 100-hp engines that allow continuous use of 100 octane low lead gas. This kit can be installed at top overhaul.

Foreign Country Homebuilt Approval - We have received requests for assistance from New Zealand, Australia, Canada, and England to provide the engineering documentation required to gain approval for amateur building. We intend to supply all these requests for stress data and static test documentation, but we must wait until after the plans are out.

Other Questions?? Each newsletter we try to answer the questions sent to us which have not been answered in previous newsletters or the information kit. If your question needs and deserves an immediate reply, please include a self-addressed stamped envelope.

VARIVIGGEN PROJECT REPORTS - Only three projects reported since January. Let's hear from the rest of you!

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Mike Melvill's mount & firewall. Note the cabin heat control box at the bottom.

Mike Melvill's, SN 115, 1st class cockpit! Note engine instruments in lower center, radios at right console. Any fighter pilot should feel right at home!

This VariViggen being built near Toulouse, France will be powered by two Microturbo jet engines (200-lb thrust each). It is being built in co-operation with the engine manufacturer as a flight test article for engine development. Expected take off and climb will be similar to a 150-hp VariViggen. Cruise should be about 190 mph: range, only 250 miles on 50 gallons!

N31VV, by Jim Cavis, SN31: All work done except canopy and outer wings.

Glass/foam composite rudder and engine mount on Jim Cavis's VariViggen. The dynafocal mount is available for $180 from Star-fire Aviation, 4225 S. 37th, Phoenix, Az. 85006

VARIVIGGEN BUILDER TIPS

Those of you with dynafocal mounts may find an interference with the cowling at the mount point. The following method is an easy way to put a streamlined "blister" on the cowl anywhere you need more room. **SKETCHES OMITTED**

Tension on the aileron control cables should not be real tight. Proper tension is only 10 to 15 lb. Adjust the turnbuckles to take out the slack, then tighten about two turns for a light snub - exact tension is not critical.

You may want to carve the center notch on F20 up higher than shown on the plans to allow the nose gear to go further up and hold more securely in the up position.

The Gougeon Brothers brochure recommends three coats of epoxy to protect wood surfaces. This is for boats! Three coats are too heavy for your airplane. Paint one full coat to interior surfaces. Finish the exterior as shown in newsletter 6.

We understand from Jim Saunders, SN 396, that some manufacturers of wood props are hesitant to build a wood prop for a 180-hp Lycoming unless the builder supplies a spacer to provide a larger bolt radius for the prop. While it is completely satisfactory for the 150-hp Lycoming, they are concerned about the bearing strength of the wood on the short lugs used on the 180-hp engines. This may or may not be a problem. If anyone knows of any problems with a 180-hp wood prop, let us know. Actually, the primary torque-transmitting surface is friction between the flange face and the prop face. If you don't believe this, run your engine with loose bolts so all the torque is on the lugs - they will fail within a few minutes running. Just kidding, of course, about doing this - Never run an engine unless you're sure the bolts are properly torqued. After installing a new prop, retorque after the first run and each 10 hours until it sets in well. Recheck torque each 100 hours. Proper torque for a prop (with a hub depth of 4" and 3/8" bolts) is obtained after the bolts take out all slack and are then turned one more full turn. This provides the correct percentage squash of the hub. If you're using a 180 hp engine, contact your prop manufacturer about prop installation.

VARIVIGGEN PLANS CHANGES

Plans page 11 and construction manual page 10 - Install F3 before F5.

VARIVIGGEN SPECIAL PERFORMANCE WING

The VariViggen owners manual gives a detailed discussion of the performance and flying qualities differences between the standard and SP wings. If you can't decide which wing you want to use, check your owners manual.

Jim Cavis is building the standard shape wings with the glass/foam composite SP structural method. RAF is working with Jim on the design details of this modification and on sizing winglets for the standard wing. The results will be passed along in following newsletters or the 2nd half of the construction manual. Jim has finished the glass/foam rudders. His report: "Construction was done in two days, mostly waiting for one side to cure so the other could be skinned. I really had fun with the new method of yours - put me on the list for some EZ plans!"

BUILDING TIPS FOR THE SP WINGS
The best way to leak-check your fuel tanks is to plug the vent and hook a standard altimeter to the feed line. Suck or blow a 3000-ft pressure difference and check that it can hold pressure for 24 hours. Do this before cutting the tank cap hole.

The two yellow sheets of the SP plans are printed on card stock paper. This is so they can be tacked to your shop wall for easy reference for the glassing methods. We feel the stippling action (step 6 on the yellow sheets) needs more emphasis since, on a given layup, about 1/2 of the time is spent stippling. Add the following words: Where multiple plies are required, the first plies may be laid up overly wet and the excess resin brought up by squeegeeing and stippling to help wet out the middle plies. The final plies are ambitiously stippled instead of adding a lot of resin. "When in doubt - stipple." Don't hesitate to stipple after squeegeeing. If you use care to not apply too much excess resin, you can do the entire layup with stippling and no squeegeeing.

When bonding the large blocks of foam with wet micro it is possible that the insulation of the foam will not let the epoxy heat escape and an exotherm can occur down in the middle of the joint. This exotherm can be hot enough to melt the foam locally and weaken the joint. We have formulated a special long pot life epoxy for the VariEze to avoid this problem. This epoxy will be on the market when the EZ plans are out. In the mean time, if you are joining large blue foam blocks using Shell epon/teta or Gougeon 105/206, you should do the bond at an ambient temperature of 65 degrees or less. This will prevent the exotherm.

SHOPPING
See the back page of this newsletter for VariViggen parts and materials. Note that RAF no longer handles any parts. You are referred directly to the manufacturer for the VariViggen machined parts. We, of course, will continue to help builders on installation problems with parts obtained from RAF distributors.

Pistol grips with switches - R. Williams tells me these are available at Goff Aircraft, 8131 E. 40th, Denver, Co 80207, but their price ($38.50) is much higher than you need to pay, if they are still available on the surplus market. Anyone know where these can be found?

The following sketches of the VariViggen exhaust system and heat muff have been previously included with the cowl installation instructions.

NEWS OF THE VARIVIGGEN AND VARIEZE PROGRAMS
(very vig-in) (very easy)

NEWSLETTER SUBSCRIPTION - $4.75/yr
OVERSEAS SUBSCRIPTION - $6.50/yr
BACK ISSUES - $1.00 each

RAF ACTIVITY since newsletter 8 has, again, been hot and heavy. All flight tests and ground tests for the VariEze were completed on May 20. The massive job of preparing and laying out the VariEze manufacturing manual was done on a six to seven-day week, 10 to 16-hour day schedule. The basic manual (section one) was delivered to the printer on June 15. We are currently on the same type of busy schedule, trying to complete the owners manual (section four) and the Continental engines installation (section IIA), before we leave for the 1976 EAA convention at Oshkosh, Wisconsin. Because of our high work load now on these items, we must ask you to continue to observe our "Saturday only" policy as far as visiting RAF to see the VariEze, at least until after Oshkosh. We will be closed for the Oshkosh trip from July 23 until August 13. Any mail orders received at RAF after July 22 cannot be processed until after August 13 and, of course, there will be no Saturday demo on July 24, July 31, or August 7.

SATURDAY DEMOS - Since November, we have had the weekly open house at RAF every Saturday, starting at noon. These demos start with a briefing at our building (100 yards S.E. of the tower building on the Mojave airport), a question/answer period, then a flight demonstration of the VariEze, followed by a brief structural demo in which we build a portion of the airplane to show the composite sandwich methods. The demos run from two to four hours. In the 31 weeks we've been doing this, the VariEze has flown and given rides on all but two occasions: once due to rain and once when we had taken the airplane to an airshow. We have never canceled a flight demo due to an airplane problem or due to the severe wind gusts that occasionally ground most light aircraft at Mojave.

We will probably continue to give the Saturday demo after we return from Oshkosh, and will probably extend it to provide more time for the structural demo. Be sure to call ahead to confirm that the demo will be given, since we will be scheduling composite structure seminars in other cities and may be gone on some weekends. If you would like to host a seminar, please wait until after Oshkosh, then contact us. We'll include a seminar schedule in the October newsletter.

We do plan a daily construction demonstration in the synthetics workshop at Oshkosh for VariEze builders. VariEze forums at Oshkosh this year have been scheduled for Monday, August 2, and Thursday, August 5. A VariViggen forum will be Wednesday, August 4. .

VARIEZE FLIGHT TEST PROGRAM - N4EZ, our Continental-powered prototype, has undergone one of the smoothest prototype test programs we have

seen. In only two months and one week (March 15 was first flight, tests were completed by May 20), the aircraft completed an 85-hour test program which included development of the engine installation, all other systems, flying qualities optimization (all cg's, all weights), performance determination (with several propellers), dive tests, spin tests, and environmental qualifications (110 degrees ramp temperature, 16,000-ft altitude cold soak, taxi/take off/landing in wind gusts to 45 knots).

No major problems were encountered during the tests. Modifications made as a result of the tests included nose gear retraction/extension system redesign, addition of roll trim (VariEzes now have three-axis trim), addition of a parking brake, modification of air inlet configuration to optimize cooling, simplification of exhaust system, and optimization of pitch and roll control system ratios. It is interesting to note that throughout the complete test program of N4EZ and N7EZ, there has been no structural rework or modification required. This involves two airplanes, over 13 months testing, and 350 flight hours. This is quite unusual; generally a prototype of a new design (even a conventional structure) will indicate a few marginal or weak areas that need local beef up/redesign/adding fasteners, etc., sometime during its tests. With the VariEze, we have used new materials, initially unfamiliar to us, and new construction methods, etc., but have found them to be so durable in service, that no failures or degradation was found that required redesign. .

SPIN TESTS - FAR 23 certification criteria require aircraft to meet certain spin recovery requirements in order to receive a type certificate. This is not required for a homebuilt and many homebuilts have not been through any formal spin testing program at all..

CP09, Page 1

One primary reason the VariEze was designed as a canard configuration was to reduce the susceptibility to departure from controlled flight and unintentional spins. Conventional aircraft are so poor in this respect that stall/spin is the most common, fatal accident cause. A contributing reason is the FAR regulations, themselves. They are very specific in spin recovery requirements (after a one-turn spin, non-aerobatic aircraft must recover within one additional turn, with recovery controls applied), but only loosely subjective with respect to spin susceptibility. If specific resistance to departure and spin were required, as it now is for military aircraft (MILS-8369 1), few general aviation aircraft could qualify, making a lot less traffic for VariEzes!

The VariEze is designed such that the canard reaches its maximum lift at an angle of attack several degrees below that for maximum lift of the main wing. Above the maximum lift angle of attack for the canard (14 to 15 degrees), the loss of canard lift produces a strong nose-down moment. The result is that the aircraft limits itself to 15 degrees and cannot be forced above that angle, regardless of cg. The aircraft also is designed to have excellent directional stability, dihedral effect, and rudder control at and above 15 degrees angle of attack, thus the airplane is not susceptible to the inadvertent departure and spin common to most conventional aircraft.

The normal operational range of angle of attack is one degree (high speed cruise) to 10 degrees (flare to land at 55 knots). Angle of attack values above 10 degrees are not required for any normal operation, but were tested to assure the safety and recoverability, if the pilot inadvertently exceeds 10 degrees.

The pilot for our spin tests was Peter Lert, an experienced pilot, who makes his living as an aviation writer for "Air Progress" magazine, and who is light enough (135 lb) to allow aft-cg testing. The following is a summary of the results of the high angle of attack testing. The VariEze owners manual will have complete details.

The VariEze's "stall" consists of any one of the following, in order of prevalence:

1. Stabilized flight (climb, level, or descent, depending on power setting) at full aft stick at about 48 knots. Below 51 knots there is a very definite increase in the aft stick force, such that the pilot has to pull noticeably harder on the stick to get below 51 knots. Below 51 knots, the aileron control degrades, but rudders still provide excellent turn control, even at full aft stick.

2. Occasionally, particularly at forward cg, the airplane will oscillate mildly in pitch after full aft stick is reached. This is a mild "bucking" of a very low amplitude, one to two degrees and about one-half to one "bucks" per second. If the full aft stick is relieved slightly, the bucking stops.

3. Occasionally, particularly at aft cg, the airplane will exhibit an uncommanded Dutch roll, a rocking back and forth of the wings in roll. The rock, if it exists, will be mild and sometimes divergent, reaching a large roll (30 degrees bank) by about the fourth or fifth cycle. The "wing rock" can be stopped immediately by relaxing off the full aft stick stop, or by using the rudders to counter the rolling motion. At any time during the "stall," power can be set at any position, or slammed to full or idle, without effecting the stall characteristics. There is a small roll trim change due to power and a very slight pitch trim change; neither effect the aircraft's controllability at sustained full aft stick. At no time did the aircraft experience a departure from controlled flight.

Accelerated stalls to three-g and steep pullups to 60-degrees pitch (min speed, 35 knots) were done at full aft stick without any departure tendency.

Intentional spins were attempted by holding full aft stick and using full rudder, with all combinations of aileron control, and at all cg positions. These controls were held through 360 degrees of rotation. Full aft stick and full rudder results in a lazy spiral which ends up in a steep rolling dive at 3+ g and 110 knots. At any time, the spiral can be immediately stopped by removing rudder control and a completely straight-forward recovery can be made. That maneuver is not a spin, since at no time is the aircraft departed from controlled flight. If the above maneuver is done at aft cg, the rotation rate is higher, so the lazy spiral is more of a slow snap roll. However, even at aft cg the recovery is immediate when controls are neutralized.

OTHER FLIGHT TEST RESULTS - N4EZ has demonstrated take off and landings in crosswind components as high as 20 knots and satisfactory taxi (all quadrants), take off, and landing in gusty winds to 45 knots. N4EZ has also flown through very heavy turbulence in a rotor cloud under a triple lenticular in which g excursions went from -1 to +3.5 g. The red line speed has been opened to 262 true/220 mph indicated, a comfortable margin (exceeds FAR part 23 requirements) even for the largest engine (100 hp) which can cruise as high as 200 true/176 indicated (at 7500 ft). Damping of all controls at the dive speed is excellent and similar to low speed. If, at a later date, we have a requirement to extend the red line to higher speeds, we will do so.

ENGINES - Cooling on the 0-200 has been excellent. Ground cooling is better than most factory-builts. At a recent flying, we had to sit in a long line on a hot ramp awaiting take off for over 30 minutes. Many of the factory-builts had to shut down to avoid over heating, but N4EZ's temperatures stayed under the normal values for cruise. The 0-200 Continental engine has been trouble-free, requiring no modifications, adjustments, or unusual maintenance. This has not been true of our VW installation on N7EZ. We have flown the VW VariEze a total of about 280 hours (two different engines), which is a lot of flying for one year for a VW homebuilt. We have had its cowling off an average of once per five flights, though, making minor carburetor adjustments, trying to find oil leaks, adjusting or repairing valves, cleaning plugs, checking the magneto coupling, tightening loose bolts, etc., etc. The VW-powered VariEze has never had an inflight power failure, but it has twice had to be landed within a few minutes or it would have had a failure: once due to low oil pressure, another time due to an impending failure of the prop hub/extension. We have conducted an informal survey and found that our VW experience is quite similar to others, who have high time on VW aircraft conversions. For this reason, and because of the high cost of operating these engines, we are not preparing the section IIB, VW engine installation, at the present time. This section should be made available by October as we gain some more reliability experience with the engines and after the results of some further tests.

Those of you who plan to use a VW do not have to delay your project. The engine installation is done during chapter 23 (of 25 chapters) of section I. All items involving changes due to engine installation are in section IIA or IIB. If you can't find an engine or haven't decided which type you plan to use, we suggest you get only section I and go ahead and start building. Chances are, you will find the right engine at the right price before you get to chapter 23.

Frankly, when we went shopping for an 0-200, we couldn't find one. We let several people know we were looking, then all of a sudden several weeks later, we had our choice of four 0-200's! When searching through "Trade-A-Plane" for engines, don't look only at the engine section. Quite often you can buy a wind damaged Champ or Cessna-150 with a lot of time left on the engine for less than a used engine! We get a lot of questions concerning the availability and cost of engines. We, of course, are not in the business of engine distribution, however, to

give you an idea of the current market, we have made up the following table, based on available prices from vendors, "Trade-A-Plane," and magazine ads. Cost per hour is basic engine cost, not including fuel and oil.

ENGINE	1 TIME AVAILABLE TILL NEXT OVERHAUL (REGULAR USE - 300 HR/YR)	2 OUTRIGHT COST FOR ENGINE	3 VALUE OF ENGINE AFTER RUNOUT	4 COST TO OWNER (2 - 3)	5 ENGINE COST PER HOUR OF FLYING
A65/A75 OSMOH	1200 hr	$1300	$ 400	$ 900	$0.75
A65/A75 half-runout	600 hr	$ 800	$ 400	$ 400	$0.66
C85/C90 OSMOH	1200 hr	$1900	$ 700	$1200	$1.00
C85/C90 half-runout	600 hr	$1300	$ 700	$ 600	$1.00
New 0-200	1800 hr	$4700	$1600	$3100	$1.72
0-200 OSMOH	1600 hr	$3000	$1200	$1800	$1.13
0-200 half-runout	800 hr	$2300	$1200	$1100	$1.38
Top of line VW conversion	800 hr?	$2600	$ 800	$1800	$2.25
"Low cost" VW conversion	100 to 600 hr?	$1300	$ 200	$1100	$2.20

PROPS - We have tested several propeller types and studied several others. Fortunately, the best prop has been the lightest and lowest cost - a fixed-pitch, all wood, two-blade, with plastic leading edge for rain erosion protection. These are available through several vendors. The owners manual (section IV) and section II will specify prop sizes, specifications and recommended vendors for all recommended engines.

The three-bladed prop tested, resulted in less take off, climb, and cruise performance, as compared to the two-bladed props. We do not plan to request our distributors to stock propellers. The reason for this is due to the large number of engine sizes available, and different prop extension configurations; it is better for the customer to deal directly with the prop manufacturer.

Those of you who are in a rush to be flying a VariEze as soon as possible, may not want to wait for section II to put in an order for a prop, since props are one of the hardest things to get without waiting several months. Thus, we are providing sizes and manufacturers for the 0-200 props we've tested. These are listed below. Other prop manufacturers may also be able to provide adequate props. Refer to the owners manual for prop sizes on other than the 0-200 engine.

Teds Custom Props	Bill Cassidy
9917 Airport Way	4652 Montview Blvd.
Snohomish, Wa. 98290	Denver, Co. 80207
56" dia 70" pitch	58" dia 67" pitch
VariEze SAE#1 flange	VariEze SAE#1 flange

Maximum speeds for the above props is identical. The Ted's prop provides a small edge in take off and climb. This is backwards from what you would think considering the diameter and pitch values, the blade design being considerably different on the two props.

NOSE GEAR RETRACTION - We told you in newsletter 8, that we were making a major change to the system that retracts and extends the nose gear, to incorporate a jacking mechanism to give the pilot a better capability of raising and lowering the nose for nose-down, parking with the pilot aboard. This system was built and installed in N7EZ, however, like the four other mechanisms used before, it was not satisfactory. It did allow the pilot to jack the aircraft up to level after entry, but the work required for him to do this (600 ft-lb) was still objectionable. The spring systems (needed to pull the strut up in flight) and the reversing system made the complete package too complicated and time consuming to build and maintain. We found that we had more complexity in the nose gear retraction system than in the entire pitch, roll, and yaw control systems combined! This was completely against the design concept of the airplane.

After, again, backing off and taking a look at the problem, we found that it is considerably easier to lift the airplane's nose up from the nose-down parked position, lock the gear down, then enter the airplane by climbing over the side, like we do on the VariViggen, using a kick-in step in the fuselage side. This allows a very simple, lightweight pushrod system to work the gear up and down, and allows an instant-acting inflight retraction/extension. The design and installation of this new system in N7EZ took only one day. It consists of a single pushrod to the gear strut from a knob at the instrument panel. The pushrod is bolted to a block which slides in guides such that it locks up or down by locking the knob in its lowered position.

We have been very pleased with the new system; it has required no maintenance and appears to be one that will not give problems, due to its simplicity. Retraction of the gear in flight consists of moving the knob out of its lock, raising it and pulling aft 6", then locking it in its lowered position (one smooth motion). Retraction/extension forces are only about 5 lb since airloads balance the gravity loads. Ground operation of the gear for nose down parking works as follows: back seater and suitcases go in while the nose is down. Manual engine starting is done while nose down on the rubber bumper (no chocks or tiedowns are required for manual start by yourself). The pilot then walks to the side of the cockpit, unlocks the gear knob, and raises the airplane to a level attitude. This is easily done by grabbing the leading edge of the canard and lifting (requires only about 30 lb, even with the backseater in). The pilot then locks the knob and uses the kick-in step to climb in. We have modified the yaw trim system to also provide a parking brake to keep the airplane from rolling (while the pilot climbs in) if the airplane is parked on a downhill slope. The new nose gear system now compliments, rather than distracts from, the overall design philosophy of simplicity and low maintenance.

VARIEZE STRUCTURE - To certify an aircraft for production, FAA requires the manufacturer to load the flying surfaces to 150% of design limit

load. After that loading, it is acceptable for the surface to be damaged beyond repair, but it must be in a condition to allow a safe landing. To demonstrate the structural adequacy of the VariEze's wing and attachment, we had someone, who had no previous fiberglass construction experience, build a wing from our plans. We mounted that wing in a test fixture and loaded it over 200% of design limit load. The wing had absolutely no damage, not even the transverse matrix cracking that occurs with composites at about 2/3 ultimate load! Just for kicks, we rounded up eight people and had them all stand on the wing - that was as many as could crowd onto the wing, but resulted in much less load than the formal test done with lead shot bags.

Structurally, the Eze has some very important advantages over conventional metal or wood: greater redundancy, less susceptible to catastrophic failure due to fatigue, less susceptible to corrosion or deterioration, higher safety factors, easier to inspect and repair and less susceptible to surface damage. With proper ultra violet protection (as shown in VariEze section V), the composite structure should outlast metal or wood in any type environment.

Do not compare the VariEze's glass/foam/glass sandwich structure to the method used on the KR-series, WAR-series, etc. The VariEze structure does not use foam to transmit primary/secondary loads, does not mix materials in a manner to result in thermal stresses, does not mix structural materials with highly different modulus of elasticity, does not seal off internal void areas where moisture can collect, does not have any bare foam surfaces that can flex and fatigue the foam, does not use a low modulus skin that results in high foam stresses, does not use inadequate skin close-outs at trailing edges and joints, etc. If you are not familiar with the structural techniques used in advanced composite sandwich design, you are in for some real surprises when you see the VariEze manufacturing manual. Don't expect the structure to even remotely resemble anything you have seen in any homebuilt aircraft!

You are going to be building sandwich panels, joints, local reinforcements, attachments, spars, compound curves, etc., very similar to those used by large manufacturers for new military fighters and portions of new airliners. The methods to fabricate the parts are quite different though, since you will be doing the work without special equipment and tooling.

CP09, Page 4

VARIEZE PLANS - You will find a sheet enclosed with this newsletter that describes the five-section package of VariEze documentation that is now being made available. Section I, the manufacturing manual (composite education, complete plans and construction manual for the VariEze, except for engine installation), is the major bulk of the documentation. This section was delivered to our printer on June 15 and should be back, ready to mail out by about July 1. We have completed the draft of section IV, the owners manual, and will have it printed and ready to mail by about July 10. We are also making a strong attempt to complete section IIA (Continental engines installation) during July. Hopefully, it will be completed before we leave to attend the EAA convention at Oshkosh. If it's not done by

then, it will not be ready to deliver until late August. Section III (avionics and lighting) and section V (finishing) will not be completed until September. Section IIB (Volkswagen engines installation) should be completed by October.

PRICING PHILOSOPHY - VARIEZE PLANS - We think that its of some interest to discuss the items considered in determining the price to charge the homebuilder for his set of plans. Plans prices for other homebuilts vary from just a few dollars over printing/handling costs, to several hundred dollars. Designers who sell plans for a small amount over direct costs, in order to sell thousands of sets of plans, generally find that they have sold the customer only the stack of paper, but not the service of assisting him to assure his success in completing his project. Often, designers will put an extremely high price on a set of plans and will thus receive about the same income, but have a lot fewer customers to assist. Sometimes a designer will do this to quickly recover development costs, without planning a long-term support program.

The VariEze plans have been priced to compliment our entire program of supporting each homebuilder's project to assure his success, and to provide a return on our investment in development costs within the next two years. About $50 of each set of plans sold, goes directly towards paying back the $100,000+ required to develop the design. We are both quite fortunate that that the airplane was developed, to a complete homebuilt program, for this relatively small sum of money. If any major problems would have been encountered, such as engine/prop compatibility/reliability, or spin characteristics, or structural failures, etc., the development costs could have been considerably higher. It is not uncommon for a new design to require three or four times or even 30 times that amount by the time it successfully completes the testing we have finished on the VariEze. It is not unusual for a new design, particularly one with marginal structure or systems, to end up costing so much for development that it is never satisfactorily completed. This is why it is impossible to market an aircraft before its development is completed.

You may note that the VariEze plans are higher cost than some of the other small, simple-airplane plans. However, considering the fact that they include a complete education of the materials and structural methods, and are a fully illustrated step-by-step manufacturing manual, they are actually quite inexpensive; for example, when compared on a page-for-page, word-for-word, photo-for-photo, or drawing-for-drawing basis, the VariEze plans cost less than one-third the price of the KR2 plans.

VARIEZE MATERIALS/COMPONENTS DISTRIBUTION - Okay, this is it; the big secret is out! The distributors we have been working with for the last nine months on the VariEze program are listed on the last page of this newsletter. Included in the list are the general items of the bill of materials that they stock. Unless you are in a big rush, wait to get your plans before contacting the distributor. Your plans has the complete bill of materials with each item specified as to its use and availability. Both the major raw materials distributors (Aircraft Spruce and Wicks) are presently preparing new catalogs, which list the specific VariEze materials. These catalogs will be available from them in early July.

We have been indicating to you in recent months that the distribution system will be able to supply all materials and components on very short notice, because of their stocking items ahead of time. They have done an excellent job in this respect, but the apparent initial demand for the VariEze may have exceeded our expectations. Certain items and materials may initially be in short supply and some delays are now anticipated. If you are planning to build your aircraft in a rush over the next few months, we suggest that you get your orders in immediately for the following items. These are the greatest potential 'bottle-neck' items that we can foresee at this time. Foams (manufacturer's recent specification revisions have delayed early high volume stocking), wing attach/quick-disconnect fittings (Brock), and landing gear struts (Jiran).

FOREIGN customers who are interested in making volume purchases to minimize import duties and shipping costs should contact the distributors directly for volume purchasing information. The distributors are equipped to handle this type of order.

VARIEZE QUESTIONS/ANSWERS - Thanks so much for those of you that have had the patience to wait for the newsletter to get your questions answered. If you have a question you need answered right away, state it, with room for our answer, and include a self-addressed, stamped envelope.

Q. My wife is 6 ft, 5" tall - can she fit in the back seat?
A. The front seat allows "stretch out" comfort (feet in front of the rudder pedals if you desire) for pilots to 6'7" and 210 lb. Back seat is comfortable for pilots' passengers up to 6'5" and 220 lb. In fact, those of you who were at the Watsonville flyin, may have seen a 6'9", 210 lb man get in the back seat, with the two full suitcases. His comment - "relatively comfortable." Even he was not pressed up against the canopy.

Q. Can one person remove/install the wings and canard?
A. Yes, the specific procedure is in the owners manual. It takes one tool and about two minutes per wing/canard. Instead of trailering, we suggest you remove one wing and store your aircraft under the wing of a Cessna in a T-hangar or in an unused corner of a larger hangar. In this way the availability and high cost of hangars can be avoided and the big job of tieing down on a trailer is avoided.

Q. What percent of construction work requires more than one person at a time?
A. Required, about 15%; desired, about 50%

Q. Can a 197-lb, 160-horse power engine be used in a VariEze?
A. No.

Q. Will you offer dual controls?
A. We plan to develop dual controls later, possibly this winter. It's not as easy as one might think. It will greatly complicate the control system and may eliminate one suitcase. The Eze is easy to fly and pilots can be checked out safely if they follow the owners manual procedure. Its hands-off flying qualities lowers the need for backseat controls for pilot fatigue relief.

Q. Is an intercom necessary?
A. No, pilot and passenger can easily converse in a normal level of conversation at cruise power settings.

CP09, Page 5

Q. How does a composite aircraft behave in a fire?
A. First of all, the VariEze's susceptibility to an airframe fire is far less than the average light plane. The flow of air through the engine area is aft and up, so an engine-area fire is drawn away from the airframe, rather than being impinged upon the firewall as in conventional installations. Also, the fire which results from a crash is generally due to oil or fuel being ignited by sparks from steel on rock, etc. The Eze's fuel tank durability and fuel line routing is a plus factor. The lack of steel items that can cause a fire's ignition source, is also an advantage. Now, if a fire does exist, the rate at which burning progresses in the glass/foam/glass sandwich structure, ranks between an all-metal airplane and a wood or fabric airplane.

Q. Minimum size door in the shop to hatch a finished VariEze?
A. If you leave the main gear off until after the airplane gets out of your shop, a 30-inchx68-inch door or window is enough.

Q. How do you air-start a VariEze without electric start?
A. Due to the high pitch of the prop, the engine windmills at all speeds down to about 60 knots.

Q. Cabin heat?
A. Drawings for cabin heat are included in section II, however, due to canopy radiant heating and the excellent insulation of the sandwich structure, cabin heat is not needed for day-VFR, even at cold outside temperatures.

Q. CAN I get color photos of the VariEze?
A. RAF has none for sale, however, Jim Jeffries Productions, Inc., has been up taking photos of N4EZ and has expressed an interest in making a color photo set available for sale. Contact him at Box 14, Santa Paula, Ca. 93060, for details.

Q. I have a 900-ft grass strip out back. Should I build a VariEze to operate out of it - it's a little rutted in the winter.
A. No. Buy a Cub or build a Volksplane. Lift off speed and landing speed of a VariEze is 55 to 60 knots (63 to 69 mph), which takes it out of the "backyard patch" category. We have increased the tire size from the prototype Eze to help its rough field capability, but the 55-knot touch down is definitely not recommended for your pasture. The best rule is this: "If you would operate an American Aviation Yankee from your field, it's okay for a VariEze."

SOME PERSPECTIVES ON ENGINE DEVELOPMENT - We are probably going to hear a lot of anguished cries from would-be engine developers, but we are taking a hard line on "other" engines in the VariEze. We have had many calls and letters from people wanting to install all kinds of converted boat, snowmobile, auto, turbocharged trash compactor, etc., engines in

a VariEze. Also, there is an interest in all kinds of unproven modifications to the VW (fuel injection, turbocharged, electronic ignition, etc.). Frankly, we're scared stiff by this. Aircraft engine development is a very risky, horribly frustrating, and enormously expensive business. Please don't kid yourself into thinking that you can do a successful engine development program in order to save money! Please don't kid yourself and think your new engine conversion isn't going to fail a few times during initial flight testing. Even a professionally trained, educated, and experienced engineering organization with a barrel of money, can't do these things, so don't try it in your garage. More over, don't believe anybody who says he can do it for you, unless he can show you excellent maintenance records taken during hundreds of hours of flying with the engine.

We are very much afraid that if a lot of homebuilders start trying to develop new engines on homebuilt airplanes, that EAA's accident record will look horrible. When that happens, look out for the FAA to really clamp down on homebuilding. We have gotten warning indications that this situation is already bad and getting worse. Doing engine development on an amateurbuilt airplane hurts everyone of us by further endangering the lenient rules that we now have. Please don't do it.

This isn't to say that some very good engines aren't hiding out there, waiting to be developed for aircraft use. We wish the best of luck to those who have the funding, ability, and ambition to do the job well. Doing an engine development job well, implies that you have the professional ethics not to endanger the hard won privileges of others.

Now, if you have an engine, it looks good to you, and you really want to prove it out for aircraft use, here's what you do: fly it. There is no substitute for flight experience. Not in a homebuilt, though!! Get yourself a Cub or Champ that is a very forgiving airplane, easy to land safely in a pasture. You are going to make several emergency landings, so plan on it. If things really get bad and you have to plant your test vehicle in the trees, then for FAA it's just another Cub that crashes, not a homebuilt. Also, you can buy another Cub and get your test program rolling again, quickly. If you had used a homebuilt, you would have to build another airplane instead of getting on with your engine development work. Once you get your new engine working like you think it should, fly the pants off it, maintain detailed maintenance records, and find out just how well it really holds up over a full overhaul period. Find out how much it really costs you to fly each hour, considering initial cost, operating costs, maintenance, replacement, and everything else. We once participated in a "low cost" engine program where the initial engine cost was less than 10% of the 100-hp Continental, but taken hour-for-hour of service, the cheap engine costs more than eight times as much! Remember, an aircraft engine is the very definition of dependability and reliability. An aircraft engine must tolerate abuse and still keep pumping along.

Right now there is a promising looking engine powering a Cub that is being considered for section IIC of the VariEze manufacturing manual. The gentleman behind this effort was originally going to do his development testing in a homebuilt Cassutt racer. Fortunately we were able to talk him into using the Cub. During the initial flights, at least four precautionary landings had to be made (this is perfectly

normal in initial flight testing new engines). In the Cub, it was no sweat; in the Cassutt (high wing loading, fast on landing, high rate of descent), it might have meant a broken airplane, possible injury to the pilot, and another statistic to hurt our EAA safety record. These fellows are to be congratulated on a very sensible, professional, and ethical test approach. Now we just hope that they are successful, so we can have an alternative to the Continental, but even if they aren't, they will have helped to preserve the good name of EAA and the freedoms we now have.

CP09, Page 6

VARIVIGGEN ACTIVITY - The VariViggen portion of this newsletter is quite short. We haven't heard much from you VariViggen builders lately, and no one has noted any plans corrections since newsletter 8. I guess you are all busy building! I understand that at least three VariViggens are nearly completed and we hope to have some firstflight reports in newsletter no. 10. Let's hear from you!! Ken Guscott (S/N 129) has a VariViggen construction article in the June 76, "Sport Aviation" magazine.

N27VV has undergone no modifications or maintenance since the last newsletter. It has only flown about 25 hours in the last three months, mostly for chase during the VariEze spin tests and for cross-country trips. Those of you who may be close to finishing your airplanes, be sure you have the VariViggen owners manual. It has very important operational data, amendments to the operating limitations and a specific recommended procedure for the conduct of your initial flights.

VARIVIGGEN PROJECT REPORTS -
Doug Dennis, SN 421, reports that he has one rudder, his canard and both elevators ready for skinning. Doug is assembling his fuselage jig and frames now. Sounds like a good start; hang in there! Doug is 15 years old, by the way!

John Poehner, SN 156, fuselage and inboard wing about ready for skinning.

Harold Reiss, SN 267, has his fuselage skinned on the sides and the aircraft is ready to turn over for bottom skinning. The instrument panel, wiring, nose and main gear, controls, seats, carpeting, etc., are installed. He started his Viggen 13 months ago.

Jim Cavis, SN 31, has his aircraft completed and painted except for outboard wing panels and canopy.

VARIVIGGEN BUILDERS' HINTS -
Harold Reiss, SN 267, is using an "A" frame made of 2x4 lumber which bolts through the four engine mount bolt holes in the firewall. He uses this to support the fuselage while it's inverted to skin the bottom, rather than using saw horses under the spar. Harold also reports that he used five, 16" door springs for each of the main gear helper springs, stretched to about 24".

Wayne Wilkins, SN 208, has an interesting method for making WR25 in three pieces so that spar E can be assembled completely off of the airplane (see photo).

More on the prop situation for the 180-hp Lycoming (see newsletter 8) - There is an excellent article on this subject in the June issue of "Sport Aviation." Note that while insufficient driving area is available in the studs, the friction face provides ample safety factors even for the 180-hp engine. Those using the 180-hp engine and a wood prop should carefully follow the recommended procedure for torquing and checking the tightness of the prop bolts at the intervals indicated in newsletter 8.

Clarification - The MG37 tube on MG14 is open at the top, not welded over (plans page 47 & 48).

Bob Tate, 4800 Mayfair Drive Oklahoma City, Oklahoma (405) 946-7839 Wants to purchase a partially-built VariViggen. Contact him.

VARIVIGGEN SP WING BUILDERS - To avoid the exotherm noted in newsletter 8, and to obtain the benefits of increased fatigue strength and low toxicity, it is recommended that you use the long pot-life epoxy developed for the VariEze. This is RAES epoxy (four or five one-gallon kits are required). This epoxy is available from Aircraft Spruce or Wicks; see last page of this newsletter.

VARIVIGGEN PLANS CHANGES
Mandatory Change Plans page 43 - The fuel system drawing (pg 43) shows the fuel valve located slightly above the level of the bottom of the tank. Revise this drawing as shown in the accompanying sketch. The fuel lines should run continually downhill to the strainer, then continually uphill to the carburetor. If there are loops that can trap air, the amount of unusable fuel will be increased, particularly during a steep nose-down descent. Add the following note to page 12 of your VariViggen owners manual: "NOTE: If a sustained steep descent is made when the fuel level is less than six gallons, a temporary fuel starvation may occur. This is characterized by a surging of the engine. If this occurs, level out and slow up (nose up, 70 mph if necessary). Normal fuel flow will resume and the engine will begin operating normally." **SKETCHES OMITTED**

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Wayne Wilkins S/N 208. Note the 2" x 3" doubler used to join front & rear halves of W.R. 25 rib.

THANK YOU FOR YOUR INTEREST IN THE VARIEZE TWO-PLACE SPORTPLANE

**PHOTOS OMITTED

THE STORY
For the last 12 months, we have refrained from promotional activities and marketing on the VariEze to concentrate totally on its development and setting up materials and components distribution. In this short time, we have 1. flown a full 350 flight-hour test program on two prototypes, one Continental and one VW-powered, 2. completed full structural qualification testing, 3. prepared a manual for the amateur builder to educate him in the structural materials and to guide him through construction, 4. set up a materials distribution system through established, competent distributors.

THE TEST PROGRAM
The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE RESULTS
The VariEze has superb flying qualities for its primary mission - comfortable travel. It has excellent hands-off stability even in turbulence. It is unusually safe at low speeds, can be flown with full aft stick (47 kt) without being susceptible to departure or spin, regardless of attitude or power. Performance is also superb - cruise up to 200 mph and climb up to 1700 fpm at gross weight with the larger engines.

THE MISSION: PRACTICAL UTILITY
Although quite compact outside, the VariEze provides unusual comfort for up to 6-ft, 7-in, 210-lb pilots and 6-ft, 5-in, 220-lb passengers, plus two medium-size suitcases and four small baggage areas. The 24-gallon fuel load allows up to 1000-mile range at economy cruise. High altitude climb is excellent, for flying over turbulence, mountain ranges, and for satisfactory high-density altitude take offs.

THE DESIGN
The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic systems design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE STRUCTURE
New composite sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, longer life, improved contour

stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair.

THE HOMEBUILDER SUPPORT
The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations. Construction seminars are provided at RAF and elsewhere.

THE AVAILABLE HOMEBUILT
Established, competent distributors have stocked materials and components before the aircraft was marketed. All raw materials are now available plus many prefabricated items including canopy, landing gear, wing quick-disconnect fittings, cowling, all machined items, rudder pedals, engine mounts, suitcases and upholstery. If you choose to purchase all prefab parts, you can build your VariEze in about 500 man-hours - really!

VariEze documentation is available in five sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full-size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words! The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, A75, C85, C90, 0-200
SECTION IIB - VW engines (avail. Oct '76)

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system, avionics, landing and position lights, antennas, starter. Avail Sept. 76

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim. Avail Sept 76

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas,

improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

The following are RAF-authorized distributors of materials and components. Items indicated have been developed under RAF approval and are recommended for VariViggen or VariEze aircraft. Contact the distributors at the address shown for his catalog and description of items. Indicate to him that you are a VariViggen or VariEze builder.

MOJAVE, CALIFORNIA 93501

Newsletter Subscription
$4.75/year
Overseas $6.50/year
Back issues $1.00 each

RAF ACTIVITY since the last newsletter has included a wide range of projects. The VariEze plans (Section I) were put on the market in early July. Demand for the plans far exceeded our expectations and at times our ability to keep up with orders. Apologies to those who had to wait several weeks for plans. Both the VariViggen and VariEze homebuilt prototypes flew to Oshkosh this year for the EAA convention. Both the VariEze and VariViggen performed in many of the evening airshows during the convention. Oshkosh was a busy nine-day event for us. Each day we had a 'builders only' discussion session at both the VariViggen and the VariEze. In addition we conducted a daily two-hour construction seminar in the work shop and three forums. We are hoping to have home-built VariViggens and EZE'S at Oshkosh '77 to take a little of the heat off of the prototypes!

Our summer has been a fast one. The Section I orders, builder support trips, etc. has really kept us at a gallop. Those of you who have ordered Sections IIA, III, and V know that they are not available yet, partly due to the summer's hectic pace and partly due to distractions. We had to do some additional flight test work on the fuel system in preparation for Section IIA. We also completed the detail design of a research airplane for N.A.S.A. utilizing VariEze technology. The N.A.S.A. airplane is a small, one-pilot test vehicle that is intended to test the handling characteristics of a future (1990's) yawed-wing airliner. We are currently proof reading Section IIA and it will go to press shortly. With allowance for printing holdups Section IIA should be available by the first of November; Sections III and V should follow in mid-November.

The VariEze distributors appear to be gaining on their back-log of orders now that the materials pipeline is filling. Aircraft Spruce and Wicks have indicated that the basic materials are now being shipped with-in four to eight weeks of order. Check with them directly for a current lead time. Ken Brock advises us that he is shipping wing fittings and has most of the nose gear parts available now. Those items which Ken doesn't have available yet are not shown on his brochures; he will notify you when they are ready.

We have firmed up our construction seminar schedule for the fall. These seminars are really just for builders and those who have at least studied the education chapter. Don't encourage a group that is just idly curious to attend; this just crowds the seminars and makes it hard for active builders to get their questions answered. If you plan to

attend a seminar and have questionable or defective parts, be sure to bring them along. Swallow your pride and let other builders profit from your mistakes.

If you want to attend any of these seminars send the contact a postcard and tell him how many in your party. If you want a reply, send a S.A.S.E.

We have heard from a couple of clubs that have been formed by VariEze builders for mutual support. One group in Minnesota is so big that they have become a special interest EAA chapter! The club idea is a good one, in that builders can better aid each other in construction problems.

We have received N.A.S.A.D. approval, class one (average amateur), for the VariEze plans.

If you want to stop by RAF and visit, give us a call first and make sure we are home. We are not able to show the prototypes on an

individual basis yet. If you want to see the airplane please plan to attend one of the seminars in Mojave or hold off until after January. We will be in a different building after January and will have a showroom/hangar where you can see the airplanes. We are a mile from our aircraft now which makes showing them individually an awkward thing to do.

MATERIALS DISTRIBUTION

In the initial rush for materials that followed our release of Section I last June, the distributors were completely swamped. Frankly there were a whole bunch more ready-to-start builders than we ever dreamed of and the result was almost immediate exhaustion of available materials. In the wake of the delays which followed we have received a few complaints from builders who have had to wait six to ten weeks for materials from our distributors and we feel that we owe everybody a brief explanation of how the present distribution system came to be.

RAF is a very small company with no desire to expand into distribution or manufacture of materials or components. When we originally started planning to market plans for the VariEze we were not going to be referring customers to any specific source for materials, since all materials were to be available in just about any reasonable-size city. We were going to build the airplane with a common industrial weave of glass cloth, with a popular Shell laminating epoxy system and with any type urethane foams, available at any well stocked building-supply outlet. We would thus be able to give the specifications in the plans and let the homebuilder find his own source of materials. When we started building N7EZ (then called the mini-Viggen) we ran into some problems. The glass layups were quite difficult in many areas and looked beyond the capability of many all-thumbs builders who would want to build one, and there was a large weight variance due to workmanship. Thanks to Fred Jiran, the glass sailplane wizard, we found a solution: specially designed weaves of glass cloth that took most of the work out of the layups, resulted in far less weight variation, and fewer man-hours than the materials we had been using. We then realized that not only would the materials be easy to work with, but also construction would be much quicker than working with conventional wood or metal. It was then that the name 'VariEze' was adopted. This, of course, threw a wrench into our plans to not market materials, since the cloth was available only in Europe and required a large special order to get it made here. We then decided to invest in a special order, sell the cloth to the homebuilder, and let him scrounge the remaining material wherever he could.

Next, we ran into several problems with the epoxy. Its toxicity was quite high (SPI-4), mix ratio at 12 percent was very critical and we were certain we would need two pot lives due to the exotherm damage we found on our high temperature insulated tests. Thus, due to the high ventilation and skin protection requirements and uncertainty of local availability of the required hardener systems, the viability of the project was in doubt. About that time we met with several composite engineers working in the advanced composite development department of a large aerospace corporation. We had a meeting at their facility and described the entire VariEze structure to them and discussed with them the epoxy problems we were experiencing. They were anxious to not only solve our problems but also to suggest that recent developments of

elastomeric - modified epoxy systems would greatly add to the fatigue life and peel strengths in our structure. We initially tried a commercially available system but found the work-ability poor due to higher viscosity and the pot life still not optimum. What followed was a long series of testing numerous variations, attempting to optimize the formulation of the epoxy system. Building components for N4EZ (the homebuilt prototype), samples for strength, environmental and exotherm tests, gave us a good basis to evaluate the system for not only physical properties but also for work-ability. The result was a system that was not only less toxic (SPI - 2) but also had considerably better fatigue and peel strengths (data are shown in an article in the July issue of "Sport Aviation").

Since marketing glass and epoxy was beyond the scope of materials distribution we were interested in, we decided to have a couple of established distributors stock the epoxy. Then came the bad news. Yes, formulators would be happy to formulate the epoxy system but the retail price would be almost $35.00-per-gallon kit, almost twice the retail price of the original Shell system and adding $200.00 to the price of the airplane. We then decided to have the distributors stock both the Shell and the new system (now designated RAE) and give the homebuilder his choice, noting that certain aspects of the construction methods and the physical properties would suffer with the lower cost material. One of the composite design engineers who had helped develop the formulation, offered to do the production formulation himself, to reduce costs over the large packaging companies and to protect his proprietary rights on the formula. We were then able to get the retail distributors to lower the normal markup for the epoxy and get the retail price down to $24.75 per-gallon kit, which would add only $85.00 over the price of the low-cost system per airplane. Thus, rather than go thru the expensive process of determining and qualifying the required hardeners for the low cost resin to obtain the correct pot life times, we decided to not delay the program and to have the distributors supply only RAE.

At that time there were other individuals offering to supply builders with various materials and were sending samples for our "approval". We learned two things from this experience: (1) It is very time consuming and expensive to do all tests required to gain confidence in a given structural material and (2) there is a very wide range of quality and acceptability in many of the materials, particularly the foams. Now that we had just solved the glass and epoxy problem we had a foam problem. We were concerned that the homebuilder would be sold inadequate foams, totally in good faith, by outlets who did not understand the importance of the proper physical characteristics

---

and of quality control. The only way we could assure the homebuilder of getting the right materials was to specify it to the distributors and follow-up to assure quality control. The foams also presented an availability problem, since only one plant in the United States manufactures the blue foam in the correct cell size and in large enough blocks. The PVC foam must be imported from Europe and is quite expensive (typical retail price for the blue and green is 50 - 60cents/bd foot; PVC is generally much higher).

With our mind at ease that the homebuilder would be able to get satisfactory structural materials, the distributors wanted to also make up a hardware and metals kit, to allow builders to avoid the hassle of rounding up the numerous other items. We felt this was a good idea but insisted that they retail any item individually.

Prices - as you may know, we had estimated that raw materials cost for a VariEze (less engine) would be about $1,400.00 and about $2,700.00 if you elected to buy a lot of the items prefab. We then set the plans price at five percent of the prefab kit price. The materials/prefab parts price estimates were too low due to several reasons: (1) availability problems noted earlier, (2) handling/packaging costs of the many small items, (3) stampeding inflation of these type materials and (4) our obsolete price lists. Every item ended up costing more than our estimate, except the landing gear struts and they went up fifteen percent last month.

As a result, the current price for raw materials from the distributors is about $2,200.00 and about $3,400.00 if you elect to get as much as possible prefabricated. Plans price is now four percent of the prefab kit price. You can still build an EZ, for a materials cost of about $1,700.00 if you don't count tools, upholstery, and if you do a reasonable amount of scrounging for items like instruments, wheels, hardware, etc. Almost daily we hear from individuals who have found A - 75 and C-85 engines for $1,000.00 to $1,500.00 with lots of hours remaining. So the $3,000.00 airplane is not impossible, just improbable! We have about $5,800.00 in N4EZ, including the 0-200 and a NavCom.

VARIEZE PARTS WEIGHTS

The following are average weights for items constructed from the VariEze plans:

CANARD (chapter 4)	16.7 lb.
Both elevons with weights	6.3 lb.
Each wing with fitting	34.0 lb.

TEST DATA

The following flight test data from VariEze N4EZ are presented for those interested. We will attempt to have a tidbit of this type in every newsletter **GRAPH OMITTED**

VARIEZE CONSTRUCTION HINTS

In general, builder's acceptance of the construction methods has been excellent. We have received very little feed-back from anyone who felt that the building skill requirements were too high. Construction problems have been in two categories: (1) failure to follow or read the instructions in the plans, (2) errors or unclear areas in the plans. Category No. (1) will always be with us and can be avoided by following all the information in the plans carefully. Category No. (2) plans errors, are being cleared up due to the excellent feedback we receive from builders who contact us to suggest improvements.

Problem: The hot wire variable control shown in the plans is not only expensive, but has been discontinued by the supplier. The hot wire control can be any power source (AC or DC) capable of six amps (for .041 wire) or four amps (for .032 wire) and adjustable from about ten to eighteen volts. The following information lists several low cost units, and one which works great that you can build for about one dollar!

(1) Anderson Engineering Co.
2216 Foggy Bottom Road
Florissant, MO 63031
Kit # AS - 1 $17.99

This is an excellent control with an easily adjustable current up to eight amps.

(2) Most model train transformers are capable of powering a hot wire of .025 or .032 dia. stainless steel.

(3) A G.E. # OI - 61 ULO light dimmer (600 watt) control (about $5.00 in electrical supply houses) will power a .032 dia. hot wire. The control is quite sensitive and uses very small adjustments in the lower range of the dimmers range.

(4) The following schematic is all that is required to heat a hot wire using normal 115 - Volt house current. **SKETCH OMITTED**

Of course, a 30-foot hot wire is a little hard to handle, and the 115 Volt can give you a good jolt. So using the same principle you can make up the control as follows, using a 1 x 12 board, some wire (made from an extension cord), some nails, .032 stainless safety wire and an alligator clip. The wire is strung across 50 nails as shown, positioned up above the wood board. The alligator clip is adjustable from the 15th to the 25th nail to control wire temperature. Cover the 1st through 15th nails to avoid shock. The wire is hottest with the clip moved closest to the 15th nail. Be sure the wires are not touching the board. This system demands about 400 watts. **SKETCHES OMITTED**

Regardless of what control you are using, be sure to set the temperature as instructed in the plans, one-inch cut every four to six seconds with very light pressure.

The paper mixing cups can be reused, even with a large amount of hardened epoxy in them - just be sure to balance your scale to level before adding epoxy and hardener.

If you need to estimate the thickness of glass buildup for a particular layup, use the following values: BID = 0.013 inches-per-ply. UND = 0.009.

When mounting the template drawings for the wing foam cores, use a straightedge to assure that the level lines are straight. If you line them up referring only to the vertical lines, it is easy to get the rib

crooked. A good spray paper adhesive like 3M-76 prevents the wrinkling caused by waterbase glues.

Some builders have noted the full size center section spar pattern is about 0.1" shorter than the length indicated by the B.L. numbers. This is caused by an inaccuracy in the reproduction process and is small enough to be ignored.

When tacking the large blocks together for the wing cores, some builders have had the five-minute leak down in the joint far enough to hang up the hot wire. This can be avoided by laying a stick of wood across the joint and applying the five-minute to the stick, well away from the foam joint.

Be sure you are checking the temperature of your immediate work area with a thermometer. If you want to slow the cure a little, a fan directed at the part will help.

Important! Some builders have indicated that they inadvertently drilled into the tapped metal insert for the canard lift tabs. We have given them the following instructions to install nuts on the inserts. Also, if you are not positive that you have good full threads on your inserts you should follow this procedure, which can be done even if the canard is completed. **SKETCHES OMITTED**

Note: The correction in the next section adds nutplates on the insert. If you have not installed the canard inserts yet (chapter 4, step 2), use the following procedure: line up the insert with the lift tab. Clamp together and drill the three 1/4-inch holes. Mark the inserts and tabs (top, front, right) so they don't get flipped over or reversed. Mount a K1000-4 nutplate behind each hole. Fill the nutplate and hole in the insert with silicone rubber (GE or Dow silicone bathtub caulk). This keeps epoxy and micro out of the threads when the insert is installed. Let the silicone dry 24 hours before installing the inserts. Now install the inserts as shown in the plans. After the step 2 cure, follow this procedure to drill the glass pad: make a stop for your 1/4-inch drill to avoid the possibility of the drill slipping into the nutplate. Drill the center hole only. Install the center bolt and lift tab. Carefully line up the tab and using the tab as a drill guide, drill the other holes. Remove the bolt, prepare both surfaces for bond and install the three bolts and tab with wet flox. The bolts will push the silicone back on installation. The best quality holes in the glass pad can be obtained if the step 2 cure is allowed to cure two to three days before drilling. An alternate method is to use the plans procedure, but substitute 1/4-inch steel for the 1/8 inch aluminum inserts.

When routing the holes for the VECS3 brackets do not gouge into the spar cap. The bolts must be removed to install the VECS3's. One builder routed the hole forward to allow the VECS3's to rotate into the notch, and in doing so, removed 1/3 of the spar cap! He had to replace his spar cap, full span.

Be sure the elevon slot in the canard is correct and true before skinning the canard bottom. Warps or high places may limit up-elevon travel.

When slicing the cross-fibers during the spar folding layup, use a new sharp razor blade. Make a light pass over the fold with the blade held as shown. Then use your brush to stipple the bubble down. Do not stroke the brush on the surface, all stippling is done as a vertical stab at the surface. This vertical stabbing motion is the majority of work in building an EZ. Brushing on resin builds up weight. Adding a little resin in a vertical stabbing motion is much better. If proper stippling is done, very little, if any, squeegeeing is needed.
SKETCH OMITTED

Shelf life of RAE is two years unopened or one year after opening container. Both are for storage at room temperature out of sunlight. Do not store urethane foam in sunlight.

Do not be concerned that the elevon template is thicker than the elevon core. This accounts for the normal reduction in core size due to 'burn down' in the hot wire cutting. Excess can be trimmed before skinning. Check the fit of the CS2 brackets before glassing the bottom. They must line up well to allow the elevon to rotate smoothly without binding or stressing the VECS3 brackets.

We understand there is a wide range in sensitivities of bubbles in levels, ie., 1/2-bubble in one level may be twice the angle as 1/2-bubble in another. Be as precise as possible in setting wing twist and relative incidence. The relative incidence measured at the mid-span point must be within 0.1 inch over the length of a two-foot level. Do not reverse the level when checking right to left wings - this allows level inaccuracies to effect relative incidences. There is no room to be sloppy here; the twist and incidence of the wings must be set accurately.

A couple builders have reported that the glass build up on the wing fittings has been too high, such that even without the tolerance pads, the last ply is higher than the WA8 tongue (page 6 - 8). This is due to one or both of the following: (1) Inadequate stippling/squeegeeing on the pad/ spar/skin layup causing an overly wet, thick layup. (2) The Brock wing fittings have a WA3 tongue which is about .015 undersize due to a machining operation. This is equal to one ply of BID. Thus, we recommend that if you are using the Brock fittings, you reduce the pad by one ply and carefully squeegee during the layup. If you do come up high, do not cut away the skin, it must be continuous under the wing fitting. Make an aluminum spacer from some aluminum sheet and install it between WA3 and WA1 to fill the gap caused by a high layup. A high layup due to excess epoxy can be lowered by applying pressure on the top plate if the layup has not started to cure. This is possible if the layup is done below 75 degrees f and with enough people so it can be completed within three hours. Never attempt any layup below 60 degrees f, since the higher viscosity of the resin will make it more difficult to wet out the cloth. A good quality layup is difficult to achieve below 65 degrees f.

A preferred method to potting the electrical wires in the wings is to install a conduit, then push the wires thru later when needed. The conduit can be thin-wall alum or plastic tube, 1/4 or 5/16 dia. Only two #18 wires are required per wing, since strobes should be mounted on the fuselage (one on top behind canopy and one on the bottom near the nose wheelwell).

Formica scraps or masonite make excellent material for templates.

Do not over tighten fasteners. Correct torque valves are #10 = 20 in lb., 1/4 = 60 in lb., 5/16 = 100 in lb.

Drill a small hole through two 1-inch lengths of 1/2-inch diameter dowel and thread them onto the hot wire. This allows you to grab the wire immediately adjacent to the template for better control during hot wire cutting. Remember, the wire must be as tight as possible and speed must be slow around the leading edge to avoid lag undercuts. A leading edge undercut as much as 1/8 inch is acceptable and can be trued up with a long sanding block after the core is jigged.

Never make a glass layup over a core that is not straight and smooth. The glass panel cannot take the loads if it has bumps, depressions, steps, etc., in excess of the allowable values. Always check your core shape and size with the section drawings in the plans to assure they are formed and aligned properly before laying glass over them.

The main gear leg as received from Jiran looks twisted. This is due to the combination of the forward sweep and camber angle. If you want to check the toe-in before mounting the gear, set it upright with the end leading edges 4 inches forward of the center leading edge. Check the toe-in on a horizontal plane. It should be slightly toed in, but not more than 2 degrees. Adjustments can be made with a coarse sanding block before mounting the axles. Make the final adjustment after the gear is mounted.

Microspheres can be put in a large spice shaker for convenient dispensing.

The trim required to adapt the Cleveland brake to the strut is shown in the following sketch: **SKETCH OMITTED**

The dimension shown should be checked on the canopy when jigging it to the blocks on the fuselage (top of Page 22-2). Adjust the forward blocks if required, to attain the 12-inch height shown. In no case should this dimension be less than 11.5 inch. This would impair forward/downward visibility during climb and landing. This dimension cannot be determined by measuring the canopy as received from Cowley. The canopy is blown into a frame that is 20 inches wide at the front and 19 inch wide at the rear. The canopy is then bent inward to a smaller width when it rests on the blocks. This causes its height to increase in the center. Do not attempt to bend the canopy in until it is trimmed as shown in chapter 22. **SKETCH OMITTED**

Refer to the following drawings for installation of the kick-in step. Refer to the Owners Manual for details on use of the step. First, cut a 4-1/2" long by 3-1/4" high hole in the fuselage side just above the lower longeron and just aft or forward of the seat belt mount. Fit the side pieces (16-1b PVC) and top piece (1/4" ply) into place after removing enough foam. A short piece of piano hinge is bolted to the plywood insert and riveted (1/8" pop rivets) to the door. A small

compression spring, (attached on each end to the door and to an aluminum bracket with safety wire) closes the door when your foot is removed. **SKETCHES OMITTED**

The following is a simple way to check the pot life of your epoxy and give you a feeling for the importance of mixing batches of epoxy only as you need them. Be sure your resin and hardener are at 75 deg F. Mix about 5 oz of epoxy, stir well and leave the cup undisturbed at 75 deg F. Be sure you use the supplied 8 oz cup. The fast epoxy should exotherm, reaching a solid block in about 30 to 40 minutes. Slow epoxy should be solid in about 60 to 90 minutes.

WING FITTINGS - Before you bond the fitting permanently to your wing-spar foam core (chapter 6, step 3), trial fit the whole wing foam core (with the fitting) in the jig. The fitting should fit flush with the inboard edge of the foam core. Check the positioning of the spar core carefully and make sure that the spar trough top and bottom is deep enough to accommodate the spar cap layup. Use the section views of the completed wing on pages 6-18 through 6-21. Make sure that the fitting is on the spar foam core straight and not cocked off to one side vertically or horizontally.

Exotherm foam damage - care must be taken to avoid heavy buildups of epoxy/micro down inside a joint that is insulated by foam, such as on the assembly of the wing cores and on the winglet mounting. The gap to be filled by micro when assembling any foam cores should not be thicker than 1/16 inch. If you try to fill a gap greater than 0.1 inch you will be adding excessive weight and, more important, the large mass of epoxy-micro, insulated by the foam, can exotherm. Heat resulting from exotherm can be as high as 450 degrees F, which will melt away the foam locally and destroy the joint. On the winglet attachment (chapter 24, step 3), wait about an hour before doing the last paragraph on page 24-2. This allows the inside layup to partially cure before installing the extra micro and green block. Feel the inside layup before installing the block to assure it did not get hot due to exotherm.

Any time an exotherm is suspected, by an expansion of the epoxy at the surface or by the epoxy at the surface getting hot during cure, the joint must be inspected for exotherm damage.

It is good practice to not only keep the gaps small, but to do large block assembly below 70 degrees F. Always use RAES on core assembly or any large-mass potting; it was specifically formulated to eliminate an exotherm. Do not substitute RAEF. The photo shows a comparison of F and S joints. Note the form damage caused by the exotherm deep in the F joint. **PHOTO OMITTED**

WORKMANSHIP AND QUALITY CONTROL
In section I we gave you detailed information on specific defects that you may find in your work and how to repair them if necessary. We went into details there and don't need to repeat them here, but it does seem appropriate to make a few comments of a more general nature on workmanship. There is no substitute for good workmanship, and no excuse for poor workmanship. We've made an effort at making the materials and techniques as easy as possible for the beginner to do well, but nothing as complex as an airplane will ever be completely idiot-proof. All of you will make some minor mistakes in the process

of building your airplane and this is perfectly normal. There are also, unfortunately, a few of you who will make serious mistakes and lots of them. All of you must remember that you are your only quality control and nobody else can do it for you. If you have questionable parts you are burdened with the decision to scrap them or use them. If you are lucky enough to have another builder nearby let him look your project over and respect his opinion of your workmanship. If you find that another builder in your area is doing poor work, please have the courage to tell him so. If we help police each other our safety record will improve and we'll be able to preserve our lenient rules. Sometimes it is hard for us to admit to ourselves that an expensive part is really junk and a second opinion may help us to decide.

Remember, a wrinkle, depression, or bump in the layup which is greater than 1/16 inch high (or low) and which is more than 20% of the chord length or 20% of the spar chord is not acceptable and requires repair. A depression can generally be repaired by filling with flox to level and laying over the entire depression the amount of glass that is underneath, lapping outside the depression a distance equal to one inch per ply. Be sure you don't layup a depression or bump in the thick main spar caps. The transition of the spar caps into the wing fittings must be smooth and without joggles. The above applies only to the flying surfaces. The fuselage and fuel tanks can have relatively large depressions or bumps without effecting structural safety.

Be aware during the finishing process that you are sanding on your structure. If a bump or corner exists it is very easy to sand through more than one ply. Removal of more than one ply in the following areas requires repair: wing, canard, winglet (more than 20% of chord) and center section spar corners or shear web (be especially careful sanding near the wing fittings).

VARIEZE PLANS CORRECTIONS/CLARIFICATIONS
We've got a lot of corrections this issue, because there are already several people who have built most of the airplane from original--edition plans, all since the last newsletter. Most of you already have most of these changes since they were sent back with license agreements and included with shipments of materials from the distributors. Several of you will also be working with original--edition plans for the last half of the project between now and January when the next newsletter is due. So, keep your eyes open for errors/omissions in the plans and keep us informed if you find them. Those of you who are working on the second-half (chapter 15 on) between now and January should send us a self-addressed stamped envelope. If we find important changes before January we will make copies, stuff your envelopes and send them out immediately. Be sure to mark "PLANS CHANGES" on the outside of your S.A.S.E. Do not send the envelope unless you are actually working past chapter 15.

Now - grab a pencil and make the following corrections in your plans.

PAGE/ITEM	
5-4, Step 6	Clarification - The notch in the canard to accept the mass balance weight consists of removing the bottom skin and the foam. Do not remove the top skin.
9 - 2, BKHD	16.5 dimension should be 18.1. If

you have already made it 16.5, do not reject it. The space can be filled with a 3-ply BID tape after chapter 11.

CP10, Page 4

---

5 - 5, Balance check	20 to 30 should be 10 to 25 deg.
16 - 1, Bracket	1.75 dimension can be revised to 1.6 to allow this part to be fabricated from the 2 inch angle supplied by Aircraft Spruce and Wicks.
16 - 1, Belcrank	Lower hole should be # 12 drill. If you have already drilled it out to 1/4 inch, use a 1/4 inch bolt when mounting the cable in chapter 19.
17 - 1, F.S.	F.S. 2.0 should be F.S. 2.15.
17 - 8, View AA	VECS 13 should be NG 13.
4 - 3, 4 - 16, Inserts	Install nutplates, three per insert over holes drilled in place with lift tabs, see 'building hints' in this newsletter.
2 - 2, Hardware	Add six K1000-3 nutplates and 12 AN426 - AD3-5 rivets.
2 - 3, Chapter 10	9.6 should be 0.6.
5 - 6, VECS2	Only one of the two aft rivets are required. See page 5 - 5.
5 - 3, Center	Trailing - edge micro fill is incorrectly shown on the top of the elevon. Should be on bottom as shown on the top of the page. Ditto for page 5 - 6.
5 - 5, 5 - 6, Weights	CS11 lead weight size is 0.6 x 0.8 x 2.0. CS10 is full size as shown, 0.8 wide.
6 - 11, 2 - 2 and 2 - 3	AN 525 - 416R - 16 should be AN 525 - 416R - 14. If you have received - 16 screws from Aircraft Spruce and Wicks, return them for -14 screws.
16 - 2, Page nos.	The missing page numbers refer to the drawings on this page (16-2).
7 - 1, 7 - 2 Winglet	Clarification: The dimensions at the top of page 7 - 1 are to rough out a block to use for the winglet. Trim the block to the dimensions in the center of the page and on page 7 - 2 to obtain the correct winglet size. 103 deg should be 103.7 deg.
6 - 16, Template D	The notch which extends from talking number 11 to about 6.2 should extend another 1/2 inch

	to talking number 5.2. This allows the wing fitting to slide in another 1/2 inch to its correct position on the wing. **SKETCH OMITTED**
2 - 2, 2 - 3, UND	Add eight yards to the total amount of UND required. Most of the shortage was due to an error in the chapter 4 estimate.
3 - 9, Step 6	'Resin' should be 'epoxy'. Also page three - ten step 7, and page three - seventeen. Plain resin is never used for anything.
2 - 2, Nuts	'AN 316 - 3' should be 'AN 315 - 3'. Distributors made this correction before shipping any hardware.
2 - 2, Tubing	List shows two pieces, seven feet long for 1 1/4-inch tube. To avoid large cut-off waste, distributors are shipping one piece 66 inches long and one piece 84 inches long.
2 - 2, Foam	Urethane green foam (Uthane 200) is no longer being produced. Distributors are now stocking Uthane 190 or Uthane 210 which is a light tan foam. Do not substitute trymer or 9005.
6 - 5, Pads	The 4" x 6" pads should be 2-1/2" x 6". The pads on 6 - 7 and 6 - 11 are correct. They can extend beyond the fitting. The sketches on page 6 - 4 do not appear to show the wing fitting at its 25-degree angle. This is shown correctly in the sketches and photos on page 6 - 5.
8 - 5, Pads	'22 plies' should be '40 plies' and '25 plies' should be '46 plies'.
6 - 8, Spar cap	Clarification: The photo at the top shows the cap extending out onto the outboard core farther than it actually does. The photo was taken for the top layup (step 8), in which the cap is longer.
7 - 3, R4 Angle	Substitute the following pattern for the R4 angles. Two are bent up, two are bent down. **SKETCH OMITTED**
22 - 4, Top sketch	Arrow from 'plexiglass' is incorrect.
5 - 5, CS3/CS11	The CS11 weight interferes with the CS3 bracket before full trailing-edge down travel on the right elevon; either mount the CS11 weight out

further on CS12, or take your Dremmel and grind some material from CS3 and CS11 to allow full travel. The CS11 weight should strike the bottom of the canard about the same time as the CS10 weight strikes the top skin inside its cut out.

Owners Manual — Owners Manual page 40, top. Add 'recheck torque of prop bolts after first run, after 10 hours and each 50 hours thereafter'. Also the table on page 33 (sample weight and balance data) is incorrect. Substitute the following. The most desirable empty cg position is at F.S. 110.

ITEM	GROSS	TARE	NET	ARM	MOMENT
RT M.	275	0	275	108.0	29,700
LT M.	276	0	276	108.0	29,808
NOSE	8	-1	7	17.0	119
BALLAST	-25		-25	40.0	-1000
TOTAL			533	110.0	58,627

1 - 1, 1st paragraph — Some early sets of plans omitted page count. Add 153 and 9.

5 - 6, CS2 — Material call-out omitted. This is not a VariEze part to make. If you want to homebuild it, use the full size drawing on page 5 - 6. The pivot with bushing must be 0.1 to 0.15 forward of the centerline of the elevon tube when the bottom of the elevon is level. The flange is 0.6 wide. Use 2024-0 0.63 thick and heat treat to T3. When mounting CS2 to the tube a washer may be required under the nut on the one that does not sit on the canard glass skins.

3 - 11, Glass taper — Slope of taper shown as 2-1/2 inches per ply should be 1-inch per ply (2 1/2 c.m.).

5 - 6, CS12, CS 3 — Material callout omitted. Fabricate from .125 thick 2024-T3, Full size pattern shown.

2 - 2, MISC — Nyloseal tubing (46 ft,) should be 3/16" x .025 Polypenco Nylaflow tubing (46 ft.)

20 - 2, YT 3 — The drawing shows this piece 1.7" long on one leg. Revise the drawing to 1.5" so the piece can be made from the supplied extrusion angle. **SKETCH OMITTED**

6-17, Wing Fittings	Material callouts omitted. All material except WA4 is 2024-T3. WA3 tongue is 3/8 inch plate, milled .003 thinner than WA5 to provide clearance. WA2 and WA1 plates are 1/8 thick. WA6 plates are 0.063 thick. WA7 tubes are 1X.035. Overall height to outside of WA1 plates is 6.0 inch. Scale other dimensions. WA4 pins are 4130 heat treat to 120KSI. Taper is 10 degree included angle. Top pins are drilled 1/4 inch. Bottom pins are tapped 1/4 X 28. The #10-32 tapped holes in WA3 should be only .35 deep. Use bottoming tap. Long bolt may have to be -51 length depending on tolerance accumulation, or an SAE grade 8 bolt can be substituted which has a longer thread length.
5-6, Tip Fairing	The small cosmetic fairing at each canard tip is not shown on the plans. This fairing is attached to the canard and fills the one-inch void outboard of the elevons. Shape is not critical, just be sure it doesn't rub on the elevons. See sketch below. **SKETCHES OMITTED**
21-4, Step 6	While your composite fuel tanks are less susceptible to condensation than a metal tank, they can still be contaminated with water from the fuel truck. The low point water drain (section IIA) will drain water only if the aircraft is in a level attitude. Since the airplane parks nose down it is recommended that drains be installed in the forward tip of the tanks as shown. It is preferred to install them during step 6, however, they can be installed (without rivets) after the tanks are closed out.

SKETCH OMITTED

After inside layup cures, remove foam
and install 1.5" dia 1/8" thick

aluminum plate with wet flox and four pop rivets. Glass 1 ply BID over rivets. Drill and tap 1/8-27 NPT. Plug to avoid contaminating tank. Glass outside as shown.

One builder interpreted the cross-hatched lines on the five shear web plies on page 4-4, as being individual strips of cloth! The shear web is, of course, five pieces sized as shown; the cross-hatched lines just verify fiber orientation.

A5 Gearmount — The landing gear mount extrusions are shown with incorrect separation between pairs. Both pairs (per side) should be separated 0.625 (5/8 inch). When installing the extrusions on page 10-5 (step 4), bolt the individual pairs together with a 5/8 inch spacer between them before drilling them into the fuselage sides, to assure alignment for the gear bolt holes. When installing the gear on the fuselage (page 18-3) if there is space left over in front or back of the tabs, fill this with an AN 970-4 washer or an aluminum shim. **SKETCH OMITTED**

8-2 Spar size — Due to the spar front and back pattern being slightly oversize and to the possibility of growth in height in assembly of the center-section spar, its thickness should be checked after step 2. This is necessary to assure fit to the fuselage longerons and to the engine mount. Locate B.L. 7.5 on either side of the centerline. The height top to bottom should be 8.2 inches at B.L. 7.5. Sand the top and bottom surfaces equally to attain the 8.2 dimension, fairing smoothly into the outside contour at about B.L. 23. Don't make waves, gouges, or notches in the foam to assure that the spar caps will be laid up straight. **SKETCH OMITTED**

10-2 Longerons — The distance between the bottom of the top longeron and the top of the short longeron is 8.5 inch. This is not clearly shown on page 10-2, but can be determined from A5. **SKETCH OMITTED**

We have been advised by FAA that our registration numbers must be horizontal, not vertical as they have been. The numbers will have to get smaller to stay on the winglet but I guess that's ok. Strike the reference to vertical format on page 1 - 5 of section I.

PUBLICATIONS
There is an excellent VariEze article in the November "Private Pilot" magazine, which covers some previously unpublished information on the program.

The October "Sport Aviation" has some VariEze photos and a writeup on our Oshkosh trip. "Sport Aviation" is the official magazine of EAA, and can only be obtained through membership with EAA: Experimental Aircraft Ass., Inc., PO Bx 229, Hales Corners, Wi 53130.

CP10, Page 6

6-1 and 6-2, Step 1	Step 1, wing foam core cutting has several obvious errors - VariEze wings sweep aft not forward! Replace step 1 with the revision shown here. You will cut 4 cores in the following sequence: RT OTBD, LT OTBD, RT INBD, and LT INBD. Each of the large blocks has one left and one right core. On page 6-12 through 6-15 are patterns for A, B, and C. The flip sides are X, Y, and Z, respectively.

STEP 1
HOT WIRE CUTTING THE WING FOAM CORES

This step will take about two hours. You need an assistant for hot wire cutting. First make the three airfoil templates A, B, C and the two spar templates D, shown on pages 6-12 thru 6-16 from plywood or sheet metal. While you're doing woodwork, make the three jig blocks E, F, and G shown on pages 6-12 thru 6-15 from 1/4 plywood. Lay two of the 9x18x67 blue foam blocks out on your work bench and nail together as shown. Remember that templates X, Y, and Z are the flip sides of A, B, and C. **SKETCHES OMITTED**

Carefully hot wire trim the blocks to the dimensions shown. Position the templates for the outboard right wing core as shown. Careful positioning is required so that enough foam is left for the inboard wing and winglet cores. **SKETCHES OMITTED**

Cut the core. Go slowly around the leading edge: pause at the marks. Don't rush the wire. **SKETCHES OMITTED**

Pull the templates off and set the whole block aside. Get the other blocks, assemble, and trim them as shown. **SKETCHES OMITTED**

Align and level templates Y and C as shown (Y is the flip side of B, Z is the flip side of C). Cut the left outboard foam core. Now, modify

template B and Y by carving out the spar trough as marked on the template. **SKETCHES OMITTED**

Flip the foam block over and position template A and Y as shown. Cut the inboard right foam core. **SKETCHES OMITTED**

Now, set the finished cores and remaining foam block aside and put the first foam block back on the table. Locate the X and B templates as shown. **SKETCHES OMITTED**

Now, cut the inboard left-hand core. Go slowly around the leading edge, pause where indicated. Before you remove the foam cores from the block, mark the waterline on each with a ball-point pen. **SKETCHES OMITTED**

Don't throw the remaining block of foam away. Store it for use in chapter 7.

NOTE: Check vertical placement of templates to allow cores to be cut out of the block without interference.

COMPOSITE STRUCTURE The photos show what's left of a sample we took to Oshkosh as a comparison between our composite and a typical all-aluminum structure. The sample consists of an all-aluminum wing, which was originally built for the canard of the Mini-Viggen (this aircraft was never completed). On the end of its stub spar we built a glass/foam/glass structure with core, spar and skin similar to the VariEze canard. We designed the composite side to be equal in weight; it came out only slightly heavier. At Oshkosh we placed a block of foam under each wingtip and asked people to walk on the combined structure. The metal wing failed at mid-span the second day. The structure was walked on during the remaining part of the show and then shipped via motor freight to California with only a cardboard cover. As you can see in the photo the metal wing has severe permanent damage in its skin surface, trailing edge spar and ribs. Under load its contour looks more like a wrinkled paper bag than an airfoil. The composite side is undamaged. Even the Texas boots on the trailing edge did not cause failure or distortion of contour. Of course, we do not recommend you walk on your aircraft wing. **PHOTOS OMITTED**

A breakdown of the sandwich core in an area on the side of the fuselage on N4EZ occurred and was noticed on the trip to Oshkosh. At first we thought it was a skin delamination, since it looked like the skin had pulled away from the foam over an area of about 3" X 6" on the fuselage side adjacent to the throttle. Closer inspection revealed that the foam had deteriorated in the local area, rather than the skin pulling away. This was in an area where the foam was only about 0.1 inch thick due to the inside contouring around the throttle. So, with only a thin core in this area, the sandwich was not rigid. If you pushed hard on it it could flex, and thus over-stress and deteriorate the urethane foam. This area was repaired on-the-spot by drilling a hole at the top

and bottom of the effected area and injecting epoxy in the bottom, allowing air to escape out the top hole until the void was full. This stiffened the originally flexible area and made it much stronger than before. The minimum core thickness on the plans over a wide enough area to allow flexing is 0.3 inch, so unless you beat on the skins you should not experience this problem. If you have overcontoured the inside skin such that you have a thin core over a wide area you can remove all foam over a small area as shown, before glassing the outsides, to relieve foam stresses due to flexing loads. This technique is already used in the plans in two areas (section A-A, B-B, page 12-2). **SKETCH OMITTED**

The Blue foam and PVC foams, due to their inherent elasticity are not as susceptible to fatigue as the urethane. We do not recommend any changes due to this experience, since they should not occur in an area or in a fashion to cause any dangerous structural weakness. Just don't beat on your airplane like we do to show its durability. Keep your eye out for any deterioration, which is detectable by skin flexibility or contour variances, and repair by injecting epoxy. A glue gun, available at any model hobby shop is ideal for this purpose. Above all, do not make substitutions in foam types. There are urethane foams on the market with only 1/2 the fatigue strength of the EZ Foam.

We get an occasional question on how the structure will behave at extremely low temperatures! The answer is we frankly do not know, but based on available information we do not expect cold temperature problems. The coldest N4EZ and N7EZ has been is minus 15 degrees C (in flight at altitude). The glass sailplane people are not aware of any cold-related problems. The flying surfaces, with all load-carrying structure at the surface are not as susceptible to thermal stress due to rapid temperature changes as are many other designs. According to materials specifications and the guidelines in the "Advanced Composite Design Guide" the structure should experience no adverse effects to below - 50 degrees F. There are several EZ's being built in Alaska. Any information they can add will be published in the "Canard Pusher." If you are concerned about a different environment (cold, humid, salty, etc.) in your area or anything unusual, you should conduct the appropriate tests to satisfy yourself of the adequacy of the product. It is, of course, impossible for us to provide all the answers, but we do our best to expose the airplane to as much testing as possible and have, and will continue to, publish any problems encountered and their solutions.

We have had a number of requests for loading data from individuals wanting to proof-load their surfaces, and from those seeking Foreign approval for the design. The accompanying data are the limit spanwise loads (5-g) and are for the worst-case cg conditions, aft cg for the wing and forward cg for the canard. Also shown is a convenient way to proof-load your canard, using a foam block and some friends. Don't do this by merely hanging it from the lift tabs. It must be supported (as on the fuselage) at the trailing edge to keep from bending the tabs. Also shown is our test of the complete wing and fitting, loaded to twice limit loading with shot bags. This load is equal to twelve 170-lb people. While demonstrating limit loads can give you a great deal of confidence, it should in no way be a reason to accept a part with poor workmanship. **GRAPH AND SKETCH OMITTED**

FAA COMPOSITE STRUCTURE INSPECTION
We have reprinted the inspection criteria that was distributed to the FAA GADO's, EMDO's and AEDO's in this newsletter for your information and in case your local inspector missed out on the distribution. You should contact your local inspector before you actually build much of your airplane. The sequence of inspections and at what items he wants to see are his own choice. Some of you early birds may find that you have the Feds looking over your shoulder pretty often until they get up to speed on the construction sequence. See page 14 of this newsletter.

In some places the local FAA inspectors have asked to see the wing shear web before assembly of the wing foam core. We don't recommend this because if the shear web layup is allowed to cure before assembly of the foam core it must be sanded dull for bonding later. The sanding process may damage the surface plies of glass, result in an inferior part to one wet bonded. If your local inspector insists on seeing the wing shear web, try to have him there to inspect it wet. If you can't arrange this, add an additional BID shear web ply full length on the fore and aft faces to be sanded after cure. Be super cautious that your shear web box isn't bowed while it cures.

FOREIGN BUILDERS
There is quite a bit of interest in the VariEze around the world and we have a few words of caution for potential overseas builders. Government regulations and limitations on homebuilts vary quite a bit from country to country. Please check with your local authorities before ordering plans, since we can't refund plans orders if you find out later that the VariEze is not approved for construction in your country or that materials are prohibitively costly or unavailable.

The shipping costs to some areas of the world are over $1300, making the costs prohibitive for many potential builders. We are looking into the availability of acceptable substitute materials. We have found that the foams are not available at all in some countries. One builder in Germany has reported success in substituting Rohacell for the 2 lb/cubic feet blue styrene foam, however, it's high moisture absorption makes it suspect. If you are searching for substitutes do not accept any material which has lower strength or other physical properties than the recommended materials shown as follows:

Blue Styrene:	Dow Chemical Co. Brand F.B. Styrofoam, 2 +- 0.2 lb/cubic feet density, cell size 1.4 to 2.4 mm.
Green Urethane:	Upjohn Chemical Co. U-Thane 200 or U-Thane 210 or U-Thane 190
Ridgid P.V.C.:	Conticell equivalent densities are available in Europe.

ENGINES 0-200-A Pusher installation in N4EZ has a total of about 150-flight hours to date. There has been no measurable increase in crankshaft end play which would reflect thrust bearing wear.

Everything looks good for the 0-200-A on the VariEze aircraft. Do not conclude from this that the 'A' model engine is suitable in other pusher aircraft. Look at your owners manual for the technical discussion on thrust loading. A.C. BOYLE, chapter 40 Designee, and A & P rated mechanic has been kind enough to offer some suggestions to those of you who are overhauling or servicing small Continental engines.

If you are overhauling an A-65, convert it to A-75. The conversion is covered by Continental service bulletin M47-16, revised 9/25/68.

Install the 100 octane valve conversion when overhauling any of the small Continentals.

Pistons, rings, valves, valve guides, rocker arm bushings, rocker arm pivot pins, and bosses on the cylinder heads should all meet new tolerances not service limits if you expect to get the full TBO.

Never have crankshaft grinding done by an automotive shop. Stick with an FAA approved regrind shop. The bearing journals on aircraft crankshafts have specific requirements that auto machine shops generally don't have the equipment to meet.

If you want to convert to slick 4000 series magnetos use slick kit #M2640 which gives the mags and hardware. Continental part #36066 drive gears are used with these magnetos.

Have your inspection (Magnaflux & Zyglo) and machine work (grinding and plating) done by a competent aircraft machine shop. Don't take chances with amateurs.

If you plan to store your newly overhauled engine over 90 days don't test run it until you're ready to put it in service. The combustion products from the run-in will cause corrosion internally. If long-term storage is planned, oil all internal surfaces on assembly, plug all openings (breather, oil pressure port, intake, and exhaust openings), and install desiccant spark plugs.

Follow the service manual's recommended run-in procedure.

Regarding the use of 100LL fuel in the low compression small continentals. If adequate (100 octane) valves are installed, plugs cleaned every 100 hr., and oil changed every 25 to 30 hours, no appreciable degradation of engine dependability should be experienced as a result of 100LL use.

VW ENGINES

We have been talking to a number of "high time" VW flyers over the last few months and the story we hear is generally one of woe and poverty. The message that we get, even from successful bug operators, isn't very enthusiastic. One high timer (800 hour) said that there were probably ten other guys who had suffered failures with VW's for each successful operator. He is using a Continental C-85 in his VariEze. Another bug operator we talked to said that in the 240 hours he was able to operate before failure, his VW cost him more dollars than a brand new 0-200 would have (at that time $3800), and he spent an hour with the cowling off for every hour he spent flying. The thing that scares us is that

both of these gents are very competent engine mechanics with plenty of troubleshooting experience and a trained ear for problems before they get serious.

On the other hand, we talked to a group of small-bore VW operators (36-50 hp) who had excellent service in motor gliders with very little hassle. Unfortunately the 36 to 50-hp engines, are too small to power a VariEze. Our present conclusion has to be that we can't encourage the use of VW conversions in the VariEze yet. We say yet because a number of development programs are underway and eventually the big-bore bug may become an aircraft power plant, but don't hold your breath waiting. If we were to recommend a VW installation currently, we would expect to see a lot of unhappy builders, a high percentage of maintenance troubles, excessive costs, and possibly some accidents. Beyond basic engine durability the VW converters are faced with devising and supporting a service bulletin and airworthiness directive (AD) system to support the operator. Frankly, Continental and Lycoming would not have the success record that they do without the customer support effort in service and overhaul manuals, AD's, and service bulletins. We do understand that the Limbach engine does have a functioning AD system and is one of the more reliable VW's around. Unfortunately, these engines are more expensive and harder to get than the Continentals.

There are some of you who are qualified mechanics, experienced with both VW and aircraft engines, and you know that you can operate a VW engine safely and reliably. If you want to build your VariEze without waiting for section IIB and a full development program, you can use section IIA as a guide and develop your own installation details. Efforts to develop and refine the big bore VW's are underway. One of the manufacturers will work on an Eze installation after demonstrating several hundred hours service in a Champ. We will monitor their efforts. If they prove successful and if they can provide adequate customer service, then we will publish section IIB. The earliest that this could happen is the summer of '77. We regret that IIB can't be published now but to do so would be an injustice to you, to EAA, and the accident record might jeopardize our lenient FAA rules. We will not accept orders for section IIB until a successful installation is developed. The VW installation we have in VariEze N7EZ does not have adequate reliability.

This is not to infer that the VW does not have its place in sport aviation. Its use can be justified in a low wingloading airplane such as a Volksplane or Pixie for recreational utility, and where a forced landing can always be successfully done. Those applications generally involve less than 50 flight hours per year and thus the cost per year for the first few years is quite economical.

LYCOMING ENGINES
We've received a lot of flack over our selection of the Continental engines for the VariEze since most models have been out of production for years. The most common question is "How about the Lycoming engines?" and this is your answer: They are too heavy. The 0-290, 0-320, 0-340, and 0-360 engines are totally out of the question.

The 0-235 models could be used only with some strict limitations. The normally equipped 0-235 is 242 pounds which is much too heavy both

structurally and from C.G. considerations. If the 0-235 is stripped (mags and carburetor only remaining) its weight can be reduced to 211 pounds which is marginal but can be lived with (as is the Continental 0-200 with alternator but no starter); the 0-235 has some advantages in lower cost, and it is available in a 100 octane-burning version. We haven't flown an 0-235 installation and it may not work out successfully, so don't rush out and sell your Continentals. Even if the 0-235 works ok, you would be restricted to no electrical system. A Vari-Eze program on the 0-235 is underway and it could become section IIC, but the earliest that this could happen would be next summer. The 0-235 produces too much horsepower and would have to be limited to lower cruise power settings. If you're unhappy about the available engines as we are, speak out! Write to your Congressmen (to Lycoming and Continental) and tell them to get on the stick and produce an 80 hp, 160 pound, under $3000 engine. The technology is available and if enough interest is generated, maybe we'll get some action. Get your friends to write and show the manufacturers how big the market is.

VARIABLE PITCH PROPELLERS

We haven't gotten too many requests for variable pitch/constant speed/adjustable props from our builders which is a tribute to their good sense and intelligence. However, for those few who have asked about them this is why we are down on them: safety, cost, weight, and maintenance. First, it is a very definite risk to install a variable pitch prop on a pusher aircraft. The development of a variable pusher prop for the VariEze could easily run hundreds of thousands of dollars and still be a failure. The cost of a proven variable prop, even if one were available would be over a thousand dollars each. The lightest controllable prop would weight about 25 pounds which would create a CG problem requiring ballast, further increasing the weight growth. The maintenance and upkeep required on a variable prop is unbelievable. Look through the FAA airworthiness directives for propellers, and you'll see what we mean. Even if you have money to burn, a fulltime mechanic on salary, and are a hairy-chested test pilot type anyway, you won't gain anything with your fancy prop. The added weight will limit your useful load. Even for gross-weight operation, the VariEze requires a larger airport for landing than for takeoff. Climb is excellent even with a fixed pitch prop. Thus a variable pitch prop would not increase utility.

TIGER VS. VARIEZE

Since I haven't flown anything but experimental types lately I wanted to fly another lightplane to get a comparison with the VariEze. So, last month I jumped in the Continental 0-200A-powered VariEze and flew to an airport in which I could rent a Grumman American Tiger, the 'hot rod' of the fixed gear lightplanes. I flew the 180-hp Tiger about 1 1/2 hours, including 5 landings, then flew the VariEze home; my impressions follow: Both airplanes taxied well, the Eze being easier to taxi in a direct crosswind. Both track well in the takeoff roll, the Tiger has higher stick forces required to rotate but both were easy to settle into climb attitude. The Eze rolled about 200 feet farther before lift-off but accelerated to climb speed faster. At the test conditions of 5000 feet altitude and 90 degrees F temperature the Eze had twice the Tiger's rate of climb (1200 fpm vs. 600 fpm). In level flight at the altitudes tested, the VariEze was about 30 to 35 mph faster than the Tiger at full throttle.

The VariEze is a more comfortable airplane to fly even though cabin volume is much less. The Tiger had to be constantly flown to keep it level in the light to moderate turbulence, whereas, the Eze could be flown hands-off using an occasional rudder input or trim adjustment. I

---

had a tired back after flying the Tiger and wanted to get out and stretch. The reclined seat with thigh supports, armrests, and lumbar support in the Eze caused no discomfort. Cockpit noise levels were about equal. The Eze's ventilation was better.

The Tiger had a mild torque-effect requiring some rudder at the climb speed and the rudder requirement increased as speed was slowed to stall. Stall was preceded by ample natural stall warning and consisted of mild pitch bucking followed by dropping of the left wing. The Eze had no noticeable torque effect with speed and the increased stick force gradient at about 51 knots was ample warning that speed was low. At full aft stick the Eze could be flown and maneuvered without tendency to depart or drop a wing, even though the angle-of-attack was excessive and totally blocked forward visibility.

Cruise visibility of the Tiger was better than the Eze, particularly forward over the nose. Both airplanes have good pattern visibility, but the Eze's forward/downward blockage hindered a good look at obstacles during final approach.

The Tiger was easier to land than the VariEze due to several factors. If the Tiger was high on final, reduction of power could produce a high sink rate and salvage the approach. The flaps were quite effective but there was a significant pitch trim change for the first 15 degrees deflection. On the other hand, if the Eze were high on final, airspeed would increase in order to get down, even with power reduced to idle. Approach speeds used in the turbulent flight conditions were - Tiger 75-80 mph, Eze 80-85 mph. The Tiger could be flared up to the numbers and when power was brought back it would immediately settle on the runway consistently where I wanted it and I could stop repeatedly within the first 1400 feet of the runway with moderate braking, one required only about 900 feet. Touchdown scatter was considerably more on the Eze. The airplane does not lose speed or settle significantly when power is reduced; it merely flies down the runway with speed bleeding off slowly. Bringing the nose up to the horizon for touchdown resulted in a touchdown speed of about 65 mph, which was about 5 mph faster than the Tiger. Once I was able to put the Eze on the numbers, but more often touchdown occurred 400 to 500 feet down the runway, once about 1000 feet when the approach was about 10 mph fast. The Tiger with its larger tires gave a smoother rollout and braking was more effective, particularly when flaps were raised during rollout. My general impression was that a comfortable runway length for landing the Eze was almost twice as long as that required for the Tiger, when all factors were considered. On the landing I overshot, I didn't get the Eze stopped until about 2400 feet down the runway.

In summary, the VariEze definitely has the edge in range, economy, cruise comfort, and performance. The Tiger with four seats, more baggage, and IFR instrumentation certainly has more utility. Its

better ability to operate from short fields also increases its utility over a VariEze. The Tiger carries twice the number of people, but the VariEze can get 2.2 times the miles-per-gallon.

With the VariEze you should plan on using a minimum of 3500-foot fields for your initial landings and after your proficiency builds up you can work yourself down to as low as 2400-foot runways. Refer to the Owners Manual for specific ground roll and obstacle clearance distances.

The excessive runway requirements of the VariEze could be reduced if a drag device were deployed to dirty up the landing configuration. We do plan to test one after we get the remaining plan's sections out. Do not ask about the progress of this item, we work much faster when we don't have to respond to questions! Yes, we are designing it to be retrofittable. No, we don't know how much it will help, or even if it will be successful.

N7EZ DAMAGED
The Volkswagen-powered prototype aircraft that served as a forerunner to the VariEze was damaged last July in a landing incident. While this aircraft is considerably different than the homebuilt VariEze (N4EZ), its structure is somewhat similar. Thus, the results of the crash durability of this airplane are of interest to VariEze builders.

The airplane was landed in a soft dirt incline, approximately 400 feet short of the runway. The main gear failed aft at touchdown (N7EZ's gear sweeps aft, not forward as on N4EZ, and is quite weak for drag loads). The right wingtip drug into the soft dirt, yawing the airplane as it left the ground in a nose-high attitude. The yaw coupled to roll and the aircraft struck the end of the concrete runway at 60-degrees bank and about 30-degrees nose-down pitch.

First ground contact was the tip of the right canard. Rather than failing the canard, it was removed from the fuselage, taking some of the bulkhead with it. The canard then tumbled down the ramp, damaging the elevon trailing-edge skin. Damage to the canard was limited to a 3 inch by 6 inch area where it first struck the concrete. With the exception of the easily repaired area at the tip, the entire canard structure is undamaged. A metal or wood equivalent structure, striking concrete at that angle at 65 knots, would have been destroyed.

Next ground contact was the nose of the airplane and the wingtip simultaneously, with the aircraft still at 60-degrees bank and 30-degrees nose-down. Wingtip damage was limited to the lower winglet surface. The nose took the major impact energy and resulted in a buckling of the structure around the fuselage under the canard mount, as the entire nose section moved back about one inch (see photos). The airplane then slid down the runway about 200 feet on the nose gear and wingtips. The bottom of the rudders, prop, and both lower wingtips were damaged in the slide. The nose gear pushrod (NG10) buckled between NG1 and NG13. The landing gear strut was not damaged.

All structure not noted above was not damaged. The upper winglets, winglet attachments, wings, wing fittings, spar, fuel tanks, fuselage, cockpit, canopy, etc., were not shifted in any way. The engine did not shift, and there were no fuel leaks. The pilot received no injuries even though he had forgotten to put on his shoulder harness.

It is quite disappointing, of course, to have the aircraft damaged, but was encouraging to obtain impact survivability data that is very favorable to the structure. This was an area that was somewhat unknown. Many of the all-glass sailplanes have a history of shattering the fuselage structure in a crash. Apparently the sandwich of glass/foam/glass used throughout the VariEze provides energy absorption, limits the damage to local buckling, and provides good pilot protection.

VARIEZE QUESTIONS/ANSWERS

We still get an occasional letter asking a question, but without a self-addressed, stamped envelope enclosed. We will assume that if a SASE is not enclosed, the writer does not want his question answered until the next newsletter; so, if you want prompt reply, send the SASE. Questions about availability cost and delivery of items handled by a distributor should be sent directly to them, not RAF. The distributor can process your questions faster if you send them a SASE too.

Question - Is any of the material and hardware on page 2 - 1 duplicated on page 2 - 2?
Answer - No. If you homebuild the prefab parts you will need to get the materials and hardware separately.

Question - By experimenting, I have found that RAEF behaves similar to RAES if it is mixed six to one ratio. Is this o.k.?
Answer - No! Never change specified ratios on epoxy. Never do anything contrary to the education section of the plans without getting complete justification.

Question - I plan to put a starter, vacuum pump, alternator, complete electrical system, complete IFR instrumentation and lighting in my Eze. Where do I put the ADF antenna?
Answer - First of all, we do not recommend that you plan for IFR utility on any homebuilt. Get out your FAR part 91 and see that an experimental airplane can operate "VFR, day only, unless otherwise specifically authorized by the Administrator" (part 91.42). Some local FAA authorities will approve IFR or night capability, but many require specific approval for each flight. The important thing is that FAA can prohibit homebuilt IFR merely by discontinuing the 'specific authorizations', not by having to change a regulation. I feel this will happen the first time a homebuilt has an IFR accident, particularly in a TCA. So, it is foolish to tie up a lot of money in IFR equipment that you may not be able to use. If you must have IFR utility, we recommend you use a type-certified aircraft. Remember, a homebuilt aircraft must be built and flown for "education and recreation only." The current United States rules are the most lenient in the world and were written to accommodate local recreational flying only. I think the best way to keep our rules is to not try to over-extend their intent and to do our recreational flying as safely as possible. Night-flying a high wing-loading single-engine airplane is not considered safe practice. Secondly, you are loading up the wrong airplane. The VariEze has only 67 square feet of wing area and is thus effected much more by weight growth than a Cub or Flybaby, which has twice the wing area. You will be much happier with your VariEze's flying qualities, performance and safety if you operate it as light as

possible. The maximum engine weight is 215 lb., which does not allow use of the starter and generator on all of the Continental engines. Basic and accessory weights for all the Continental engines are shown in section IIA. Due to fuel system requirements you cannot use the engine-driven vacuum pump. If you must use a vacuum instrument, you must use a venturi to drive it. Remember, due to the aircraft's small size it is not adaptable to heavy installations. The 215 lb. value is an absolute maximum. The 170 lb, A - 75 is preferred, and was the design point. The A - 75 is probably the best engine for the VariEze. Now, back to your original question, the best place to put the ADF antenna is on a Type-Certified airplane.

Question - I am learning aerobatics. What maneuvers and entry speeds do I use for the VariEze?
Answer - You are using the wrong airplane. The VariEze was not designed for aerobatics and thus an aerobatic test program has not been done. To clear you for aerobatics, I would have to conduct a complete series of tests including inverted maneuvers, tailslides, 6-turn spins, expansion of structural maneuvers, etc. I do not plan these tests because I have no requirement or intention to clear aerobatics.

Furthermore, the introduction of an all-composite structure to homebuilding is a big enough step in itself, considering the wide variety in workmanship. It would be unwise to introduce a new-type structure in an aerobatic airplane, particularly one in which inexperienced aerobatic pilots would operate. This is not to infer that an all-composite airplane has no future in aerobatics. I just think it is wise to gain several years experience in a non-aerobatic airplane first. Do not exceed the placards/limitations in the owners manual. If you are considering aerobatics, do them only in an aircraft approved for them.

Question - I am a Ham radio operator. Can you set up a frequency and time for Hams to discuss VariEze?
Answer - Ivan Whitehouse, Goldendale Wash, reports they are using 3900 khz at 8:30 P.M. Tuesday nights.

Question - Is it possible to hit the wingtip on the ground during landing?
Answer - Yes. It happened to N4EZ once. I was making an approach to Dalhart Texas on the way to Oshkosh on a gusty afternoon. On short final the airplane had a very large turbulence upset. I recovered to level flight and continued the approach. In the flare for landing I encountered another large gust which drove a wing tip into the ground and gave me a very hard touch down. The landing was quite hard and due to the shock and noise I thought I may have broken the prop or gear. I taxied in and found that both lower winglets had struck the ground. Everything else was o.k. One of the lower winglets had been shortened about 1/2 inch and was split on one side. The other had been ground off about 1/4 inch. Repair was easily done with some 5-minute and a spray can of paint.

Question - I have enclosed a sketch showing my solution to hooking up a dual control setup on my VariEze so I can make it easier to check-out my friends. Will it work o.k.?
Answer - No. Dual controls for the VariEze are not as simple as just rigging a mechanism to the back seat. First of all, we are concerned that with dual controls many will be attempting to use the airplane as a trainer, checking out people who do not meet the qualifications shown in the Owners Manual. This goes for any homebuilt - get your basic proficiency in Type-Certified training aircraft. Do not risk EAA's safety record by learning flying skills in a homebuilt. A very large percentage of homebuilt accidents can be traced to a lack of basic pilot proficiency. Second, the VariEze's roll rate due to rudder is higher than that due to aileron, thus it is important that the back seat instructor has good rudder control. The back seating is arranged such that the passenger's foot sits flat on the inclined floor, making it difficult to provide good rudder pedal control for a tall instructor. Back seat controls would require a major structural addition to the fuselage and would eliminate one suitcase. When we do provide back seat controls we plan to also incorporate rear wing ailerons to improve the roll flying qualities, since if we're going to complicate the control system that much, we might as well go all the way! The rear wing aileron addition is a very major change that affects wing stiffness and would require extensive flutter qualification. Do not build a VariEze if you require dual controls (with the assumption that they could be worked out). They may not work. Do not ask how the dual development is working out. If it is successful details will be provided immediately.

Question - I plan on notching into the wing to make the roll trim tab flush. Is this o.k.?
Answer - No. Do not modify the wing. Changing its stiffness would require extensive flutter qualification.

Question - On chapter 6 step 9, which fasteners do you prefer?
Answer - The AN 525's are highly desired since the precision countersink operation is not required. Performance loss with the external screw heads is less than 1/2-mph speed.

Question - I know my VariEze elevons should go trailing-edge-up 27 degrees, but I got something crooked & mine hit the canard at only 25 degrees. Do I have to start over?
Answer - No. 27 is preferred, but you can accept as low as 24 degrees. If less than 24 degrees is obtained you will have to adjust CS3. Do not adjust CS2. The position of CS2 relative to the elevon is important to provide the correct stick forces.

Question - Can I get a list of those in my city who are building a VariEze?
Answer - We don't have a geographic list, but you can find other builders by speaking up at your next local EAA chapter meeting.

Question - I understand from an article by Glenn Sievert in the October "Sport Aviation" that Dynel fabric has better flexural strength, but less tensile strength than glass. I have some Dynel left over from another project. Can I substitute it for glass?
Answer - No. Mr. Sievert's "comparison" of Dynel and glass tensile strength which shows glass 2.6 times as strong as Dynel is very

misleading. He has selected equal cloth weights, but in fact, due to Dynel's thickness and "burlap" consistency, it results in a lamina that is 3.5 times as thick as the 100-gram cloth per ply, and proportionately heavier. In a correct comparison (in lb/square inch tensile strength) the epoxy/glass lamina is over ten times as strong as an epoxy/Dynel lamina. The foam core in his tension sample cannot be assumed to carry its share of the ultimate tensile strength due to the greatly different modulus of elasticity; ie., the foam will not be highly stressed until after lamina failure. His "flexural ultimate" test is not really a test of the lamina flexural strength, because due to his test setup, the compressive allowable stress of the foam core was reached long before approaching tensile/compressive allowables in the lamina. In fact that his .014 thick Dynel lamina spread the foam compression load over a larger area than the .004 thick glass lamina, resulted in a higher foam core buckling load for the Dynel. The Federal Test Method used could be done on a multi-ply lamina of Dynel or glass without the core and would result in the correct values of flexural ultimate for the material in which glass is again over ten times the strength of Dynel. If Dynel were used for the VariEze spar caps the caps would have to be over one-inch thick where the glass caps are only 0.1 inches thick.

AMATEUR DESIGNERS

Composite structure, as we have said many times, is not adaptable to amateur design practice. The simplified (sometimes eyeball) design methods that have evolved through the years of experience with steel tube, simple wood, and aluminum structure do not exist for composite structures. The structural composite is the baby of all aircraft structures and it will need the years of service experience that the older materials have had to mature before the common practice and "thumb rules" for amateur design evolve. Remember, steel, aluminum, and wood have had 40 to 70 years to mature as aircraft structural materials. Composites have scarcely even flown as primary structures. The best qualified engineers in the field are still arguing among themselves about the design criteria for composites, and if the true experts are still not set on the best approaches, the amateur shouldn't even try. If you aren't a well-qualified structural designer with a good composites background, don't even consider the use of composites in an original design of your own! Unfortunately, a few foolhardy individuals have already attempted to use composite structures in aircraft without adequate knowledge and the results have been catastrophic. In mid-July the prototype of a foam/dynel/epoxy airplane had a catastrophic in-flight structural failure. The impact killed the pilot/designer/builder but fortunately nobody else. The FAA's post crash investigation revealed errors in both design and workmanship that would give a competent composites engineer prematurely gray hair. Specifically, the full depth foam leading edge (about 30% of chord) was not structurally attached to the spar and incapable of transmitting shear loads to the spar. The only thing holding the first 30% of chord to the wing spar was the dynel/epoxy skin, and the skins had been virtually sanded through in pursuit of a nice exterior finish.

SHOPPING

The following individuals or companies have contacted us indicating that they have Continental engines for sale. We cannot endorse them since we haven't seen the engines, but we are referring you engine hunters to them as a possible source.

J.W. Duff Aircraft Co. - all types: A65-0-200
8131 3 40th
Denver, Co 80207
(303) 399-6010

(612) 776-1145

Wes Winter - new 0-200A
6910 N Stardust Cir.
Tucson, Az 85718
(602) 297-4125

Ray Phillips - four runout A-75's/$450 each
291 San Bernabe Dr.
Monterey, Ca 93940

Radio Systems Technology now has a build-it-yourself VHF 2-channel (Heath kit style) radio for about $200. Looks like a real good way to keep operating out of your local airport after FAA moves their tower in. Contact them at Box 23233, San Diego, Ca. 92123.

George Evans and Bill Campbell now have VariViggen fuel tanks. The photo shows some of the VariViggen metal parts from Bill Campbell (next page).

Spraylat is no longer available in small quantities at the address in chapter 22. Contact Cowley for Spraylat.

Rich Steck (Eze S/N 662) has made up a handy logbook to serve as a complete diary of the VariEze construction to keep track of your materials and building times. It also helps organize FAA papers, changes and includes a guest register. He will sell you a copy for $3.50. Contact him at 536 16th Ave, N.E., St. Petersburg, Fl 33704.

Jerry Trump (VV S/N 313) has new Ford window-lift motors for $47 each, in shipset quantities. Also, LS-806 pulleys for $2.75. Contact him at 322 N Mountain, Monrovia, Ca 91016.

Jacket patches are not shown in the RAF product sheet. They are three inches high, three-color and consist of a shield outline with a planview of the airplane. Specify VariEze or VariViggen. They are $1.95 each.

I understand that Moorabbin Aircraft Spares, Box 68, Cheltenham, Victoria, Australia, has in stock many of the materials and hardware items for you Australian VariViggen builders.

Jesse Wright (see distributor's list) has made up a comprehensive list of parts and description with the prefab VariViggen wood parts he

sells. Those VariViggen builders who are just now starting construction should send him 50 cents for his list. Prefab parts can save a lot of work.

VARIVIGGEN ACTIVITY

N27VV made its annual flight to Oshkosh again this summer. The VariViggen prototype has flown to the EAA convention the last 5 years. It has undergone no modifications since the last newsletter. Flying time since newsletter No. 9 was only about 40 hours. No recurrence of last years landing gear problems have been experienced. The 0-320 Lycoming now has about 2000 hours since major, the entire run without problems or unusual maintenance. We did encounter a fuel problem on the way back from Oshkosh. The engine surging during descent that had occasionally been noticed (see newsletter No. 9) started to get worse. When the fuel starvation started to occur in level flight we knew something was wrong! Closer inspection revealed that the fuel screen in the gascolater was clogged with a green substance that appears to be the sloshing compound used in the fuel tank. There had been no breakdown of the sloshing compound (an approved zinc chromate type) over the previous 4 years. The airplane has just recently started to use 100LL fuel occasionally, so possibly a compatibility problem exists. We don't really know, but we are sure going to check our fuel filters more often. After cleaning the screen there has been no recurrence of the surging, even in steep descents. About 15 of those building the VariViggen got rides this year at Oshkosh.

VARIVIGGEN PLANS CHANGES

S.P. WING PLANS	Note caution on epoxy exotherm discussed in the VariEze section of this newsletter. Page 27-1.75 dimension should be 3.5.
Plans pg 5	AN4-21A (18) should be AN4-22A (46)
Plans pg 26	AN4-21A should be AN4-22A.
Plans pg 42	Some builders have found that RB2 interferes with WS30. Before drilling in RB3 check this and move inboard if required.
Plans pg 53	The wiring diagram results in the three green lights going off when there is weight on the gear (squat switch) (Harold Reiss I owe you a Coke!) While this is not standard practice it is actually a good system since the squat switch is checked on each flight and the "three green" indication on the ground can be checked by flipping the "squat-override" switch.

Harold Reiss (s/n 267)

Harold has finished everything but the outboard wings and canopy. He is using composite wings and rudders. He suggests stiffening the V2 channel when using the composite rudders, since they do not use full-span hinges and some local flexing can occur. Refer to the accompanying sketch. **SKETCH OMITTED**

VARIVIGGEN PROJECT REPORTS

Jim Cavis (s/n 31)

The two photos show (1) the front half of the two piece canopy. Sure gives his Viggen a better look than N27VV. (2) Jim's standard wing using composite construction. Note the shorter aileron span. The aileron will be balanced similar to those on the S.P. wing. If this configuration works, Jim plans to provide construction details in the second part of the construction manual, which may be available sometime this winter. By the way, Part 1 of the VariViggen Construction Manual was inadvertently omitted from the product sheet included in this newsletter. It is available from RAF at $18.50 ($20.50 overseas). Maybe we can get Jim to also show construction details on that pretty 2-piece canopy. **PHOTOS OMITTED**

Charles Allen (s/n 27)
Charles moved the main gear retraction motor assembly forward 5 inches to provide better cable access (as suggested in newsletter No. 7). He built a new bulkhead in front of F152 and tied it into the WR12 ribs with gussets. The photo shows the installation of the motor gears and extra pulleys. He plans to provide turnbuckle access through an inspection door on the bottom skin. He used Boston chain on the nose gear and used the NG1 spool as an idler to adjust cable slack. **PHOTO OMITTED**

Jack Rosen (s/n 402)
Jack has eliminated the gears on the nose gear system by a two-stage #25 Boston chain drive. The upper sprocket mounts on the AN5 bolt through the belcrank bearing shown on the plans. The upper and center axles mount to a reinforcing plate on F31 that consists of 1/4 inch ply and 1/8 inch aluminum. The 5/16 inch belcrank bearing on the center pivot is adjustable to adjust both chains. Boston sprocket numbers are shown on the photo. **PHOTO OMITTED**

Harold Reiss' instrument panel layout. **PHOTO OMITTED**

Metal parts from Bill Campbell (see shopping) **PHOTO OMITTED**

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Design ultimate load on VECS 3 and attachment.

The static load produced no failure, so we tried a dynamic test load. VECS3 shows no indication of loosening after 5 or 6 good bashes, so we tried wrenching it out with pliers, and failed CS3 first.

Static load testing the winglet to wing joint.

Phil Testa receiving the first set of EZE plans on June 26.

Phil Testa's EZE project in early September!

T. Bailey, (EZ S/N 138) constructed the handy roll-around unit for building his EZ shown in the photo. Note the handy storage and valves for easy dispensing and the electric drill for mixing.

What'a ya mean, your EZE is shinier than mine?

Static loading a production gear leg.

Oshkosh workshop. Sometimes it was hard to get your questions answered.

3:40-3:00-5 tire mounted on the Cleveland 5" wheel.

Comparing the 4:10-3:50-5 and 3:40-3:00-5.

This bizarre contraption is the roving impregnating machine designed and built by Fred Jiran for VariEze landing gear production.

No Martian. One of Fred's troops cleaning up a main gear leg before delivery.

The following information has been distributed to all FAA offices responsible for homebuilt inspections and to those foreign inspecting authorities requesting it:

AMATEUR-BUILT VARIEZE INSPECTION CRITERIA

1.0 Scope
This document has been prepared to assist inspection personnel by providing recommended acceptance criteria and acceptable repair practices for the VariEze amateur-built composite sandwich structure.

2.0 Background Information

2.1 Design Criteria
The materials, methods, and practices employed by the amateur builder in the construction of the VariEze type are new to light aircraft construction and may be unfamiliar to the inspection personnel involved with the licensing of amateur-built aircraft. Structural design criteria for the VariEze exceed F.A.R. part 23 requirements. In-house component testing of the primary flight structure has been conducted to 200% of design limits. Detail documentation of test data is on file at Rutan Aircraft Factory. The aircraft is considered to be a utility category aircraft. VariEze builders are being supplied with a complete owner's manual which specifies all placards, operating limitations, normal & emergency operations, flying qualities, maintenance specifications, inspection procedures, & initial flight test procedures.

2.2 Structural Approach
The basic structure throughout the design is a composite sandwich of load bearing fiberglass skins separated by a light-weight foam core. While the materials and processes are tailored

to the amateur builder, the structural layout is very similar to the honeycomb composite structures utilized in military and transport type aircraft and fiberglass sailplanes. Loads are carried by Epoxy/"E"-type fiberglass lamina. Foams of various types and densities are employed as a form (upon which the load bearing material is shaped) and as local buckling support. In no instance are foams used to transmit primary loads, as is the case in some other amateur-built designs.

2.3 Inspection Techniques

The transparent nature of the fiberglass/epoxy material allows for visual inspection of primary structure from the outside prior to finishing. Defects in the structure, as described in paragraph 3.0, are readily visible even in the deepest laminate.

2.4 Inspection Sequencing

The external visual inspection capability provided by the materials allow inspection of all primary structures at any point before finishing. All primary structures are at the surface, eliminating the requirement for "pre-cover" or "closure" inspections. Opaque filler materials are used throughout the airplane in finishing. and inspection must take place before any areas are obscured. Some areas may have opaque materials applied to one surface where the structure is inspectable from the opposite side (wing trailing edge for example).

3.0 Defects

3.1 Voids

Interlaminar voids in a new layup may be due to small air bubbles trapped between plies during the layup. These void areas look white and are distinctly visible even deep in a cured layup. Interlaminary voids up to 1 inch in diameter do not require repair, as long as they do not consist of more than 5% of the surface area.

Interlaminar voids (air bubbles) up to 2 inches in diameter are acceptable when repaired as follows: A small hole is drilled into the void and epoxy is injected into the void area. Small voids such as this may occupy up to 5% of the laminate surface area.

Voids greater than 2 inches in diameter should be repaired as shown in paragraph 4.

3.2 Lean Areas

Areas where the epoxy/glass matrix is incomplete because of inadequate wetting of the cloth with epoxy (lean areas) are speckled whitish in appearance. The fully wetted laminate will have a consistent transparent greenish appearance. Epoxy lean areas are acceptable, as long as the white speckled area is less than 10% of the

surface area. White-to-green ratios greater than 10% require rejection or repair as shown in paragraph 4.

3.3 Rich Areas
Resin richness primarily adds weight to the laminate. While some degradation of physical properties does occur, a overly wet (rich) layup is not grounds for rejection.

3.4 Inclusions
Bristle paint brushes are used throughout the layup process. As a brush begins to deteriorate it will shed some bristles into the laminate. The bristle inclusions, up to 20 bristles per square foot, are not cause for rejection. Occasional inclusion of small woodchips or other small foreign objects is not grounds for rejection.

3.5 Fiber disruption
In all instances, it is good practice to have the glass fibers lying flat and without wrinkles. Major wrinkles or bumps along more than 2 inches of chord are cause for rejection in the wings, canard, and winglets, particularly on the upper surfaces (compression side). Disruptions greater than 2 inches require repairs per paragraph 4.
SKETCHES OMITTED

3.6 Finishing Damage
Damage to the external structure by sanding in preparation for surface fill and paint can occur. Occasional sanding through the weave of the first skin ply is not grounds for rejection. Sanding through areas greater than 2 inches in diameter completely through the first ply or any damage to interior plies must be repaired in accordance with paragraph 4. A damp rag passed over the sanded surface will make the plies show up to determine how many plies have been sanded away.

3.7 Service Damage
Damage to the glass structure will be evidenced by cracked paint, or "brooming" of glass fibers. Both of these indicators are clearly visible. If either type of indication is present the paint and filler should be sanded away, bare laminate inspected, and repairs made per paragraph 4 as required. Where surface damage has occurred it is also likely that local foam crushing has been inflicted.

3.8 Delaminations
Delamination of glass/epoxy lap joints is evidenced by physical separation of plies. These defects are easily visible and easily repaired. The leading and trailing edges of flying surfaces (wing, canard, winglets) should be free of delaminations.

3.9 Multiple Defects
Where multiple types of small defects occur

in a laminate (voids, fiber dislocations, and lean areas for example). They should not exceed a total of 10% of the surface area of the laminate, or 20% of the wing chord at any one spanwise position.

4.0 Repairs

There are seldom single defects so massive that a major component must be scrapped. The repair procedures described here may be applied throughout the VariEze and VariViggen SP composite sandwich structures.

4.1 Small Void Repairs

Voids up to 2 inches in diameter may be repaired by drilling a small hole into the void and injecting the void full of epoxy. A vent hole opposite the injection point is required to allow air to escape.

4.2 Large Defects

Excessively large voids, lean areas, finishing damage, fiber disruptions, major fiber wrinkles, or service damage may be repaired using this procedure. Remove the rejected or damaged area by sanding or grinding and taper the glass laminate on a slope of approximately 2 1/2 cm per ply in all directions. The plies are visible as the sanding is done. The tapered glass edges and surrounding two inches of glass surface must be sanded completely dull. Damaged underlying foam should be removed and the void filled with a dry microsphere/epoxy mixture or a replacement foam piece. The damaged area is then laminated over using the same type and orientation of glass plies removed, each ply lapping onto the undamaged glass at least one inch. The whole repair area is covered with an additional bidirectional glass ply. **SKETCHES OMITTED**

4.3 Delaminations

A delaminated joint should be spread, the mating surfaces sanded dull, gap filled with flox (epoxy/flocked cotton mixture), then clamped shut while it cures.

5.0 Materials

Since a wide range of similar appearing materials exists which exhibit substantial differences in physical (structural) properties, Rutan Aircraft Factory has established a distribution system to provide the amateur builder with proven acceptable materials. RAF strongly discourages the substitution of materials. Homebuilder substitutions for the basic structural materials constitutes major structural modification to the VariEze design, and could adversely effect flight safety.

6.0 Applicability

These acceptance criteria are different from and, in some cases, much looser than for similar structures found in sailplanes and other contemporary composite structures. These criteria apply only

to the VariEze and VariViggen structures.
Design safety factors in excess of three enable
somewhat relaxed acceptability criteria compared
to other similar structures.

CP10, Page 14

BELOW IS VARIEZE SALES BROCHURE

THANK YOU FOR YOUR INTEREST IN THE VARIEZE TWO-PLACE SPORTPLANE

**PHOTOS OMITTED

THE STORY
For the last 12 months, we have refrained from promotional activities and marketing on the VariEze to concentrate totally on its development and setting up materials and components distribution. In this short time, we have 1. flown a full 350 flight-hour test program on two prototypes, one Continental and one VW-powered, 2. completed full structural qualification testing, 3. prepared a manual for the amateur builder to educate him in the structural materials and to guide him through construction, 4. set up a materials distribution system through established, competent distributors.

THE TEST PROGRAM
The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE RESULTS
The VariEze has superb flying qualities for its primary mission - comfortable travel. It has excellent hands-off stability even in turbulence. It is unusually safe at low speeds, can be flown with full aft stick (47 kt) without being susceptible to departure or spin, regardless of attitude or power. Performance is also superb - cruise up to 200 mph and climb up to 1700 fpm at gross weight with the larger engines.

THE MISSION: PRACTICAL UTILITY
Although quite compact outside, the VariEze provides unusual comfort for up to 6-ft, 7-in, 210-lb pilots and 6-ft, 5-in, 220-lb passengers, plus two medium-size suitcases and four small baggage areas. The 24-gallon fuel load allows up to 1000-mile range at economy cruise. High altitude climb is excellent, for flying over turbulence, mountain ranges, and for satisfactory high-density altitude take offs.

THE DESIGN
The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic systems design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE STRUCTURE
New composite sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, longer life, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair.

THE HOMEBUILDER SUPPORT
The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations. Construction seminars are provided at RAF and elsewhere.

THE AVAILABLE HOMEBUILT
Established, competent distributors have stocked materials and components before the aircraft was marketed. All raw materials are now available plus many prefabricated items including canopy, landing gear, wing quick-disconnect fittings, cowling, all machined items, rudder pedals, engine mounts, suitcases and upholstery. If you choose to purchase all prefab parts, you can build your VariEze in about 500 man-hours - really!

VariEze documentation is available in five sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full-size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words! The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, A75, C85, C90, 0-200
SECTION IIB - VW engines (avail. Oct '76)

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system, avionics, landing and position lights, antennas, starter. Avail Sept. 76

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim. Avail Sept 76

	Gross Weight	1700 lb

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

The following are RAF-authorized distributors of materials and components. Items indicated have been developed under RAF approval and are recommended for VariViggen or VariEze aircraft. Contact the distributors at the address shown for his catalog and description of items. Indicate to him that you are a VariViggen or VariEze builder.

RAF ACTIVITY Since October has been concentrated in several areas. All remaining sections of the VariEze plans were completed and backorders filled. We brought N4EZ (0-200-powered VariEze) into the shop for the first time since it was built and made some modifications. The plan's-configuration, manual nosegear system was installed (it had earlier been tested on N7EZ), the stiffer main gear was installed, a new fuel system incorporated, a landing airbrake fitted, and Cleveland main wheels were installed. All those modifications have been flight tested with very satisfactory results. The landing brake makes the airplane easier to land and makes short runways more acceptable. We found that we had been using an incorrect combination of Gerdes brake cylinders and Rosenhan brakes. Rosenhan brakes have a smaller cylinder and must be used with Rosenhan master cylinders (1/2-inch cylinder dia.) for good brake effectiveness. The original main landing gear strut on N4EZ was a wider tread and was more flexible, which allowed the airplane to ride quite low with reduced wingtip clearance. The strut was redesigned back in May before drop tests and before Jiran produced the homebuilt gears. The new gear, now installed on N4EZ, raises the airplane about four inches in the back, improving wingtip clearance without compromising taxi handling.

Recent flight tests with N4EZ have included more stall tests to evaluate any effects due to the landing brake, and ?????? to several small airports to evaluate runway requirements.

There were several things about the VariEze fuel system we were not completely satisfied with: first, the need for a pump to backup the normal operation of the header tank; second, the possibility of foaming the fuel in the vibrating header tank mounted on the engine; and third, the inaccurate indication of the last few usable gallons of fuel. The new system, which is detailed in this newsletter, solves all these problems and increases effective fuel head to the carburetor, since the header tank is removed. The only disadvantage of the new system is that Burt Rutan is now stuck with several hundred header tanks and fuel valves.

Some of our time has also been spent on further design work of the NASA AD-1, a small, all composite (foam and glass) research aircraft, using the skewed-wing concept. The AD-1 is a 15%-size manned, flying model of a Boeing-designed transonic airliner.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

New landing airbrake on N4EZ

Cleveland Brake Installation on N4EZ - It probably would be a good idea to rotate the brake up a little higher than this to allow clearance with a flat tire.

The VariEze construction seminars have been very successful. Since October we have conducted ten seminars around the world with over 2000 people attending! Hopefully those 2000 will share their experiences with others and the need for long-distance education will begin to taper off. We plan to conduct only four additional seminars, the dates and contacts follow. If you are building or going to build a VariEze, be sure to attend one.

February 5		Snohomish, Washington
	Contact:	G. Carter Miller 4912 Senic Terrace Yakima, Wa. 98908
February 18 and 19		Denver, Colorado
	Contact:	Bill Cassidy 4652 Montview Blvd. Denver, Co. 80207
March 27		Anderson, Indiana
	Contact:	Mike Melvill P.O. Box 561 Frankton, In. 46044
April 2		St. Paul, Minnesota
	Contact:	George B. Wilson 2924 108th Lane NW Coon Rapids, Mn 55433

Please contact the people organizing each seminar a week or two in advance of the seminar date. Be sure to include a self-addressed, stamped envelope. They will send you a flyer describing the seminar. The seminars held this fall had two to three times as many people attend, as had contacted the organizers! The more the better but it helps to know that you're coming!

N27VV, the VariViggen prototype, has done a little local flying and attended the Chapter 49 Fly-In breakfast but that is all. N7EZ is still dormant but will be prepared for some serious distance record attempts. Its distance capability in class C-1A is about 3300 miles.

Every day we get a few calls asking if any homebuilders are flying yet. The answer is no, not yet, but soon. The Wicks Organ Company airplane, the Cowley's airplane, and half-a-dozen other builders may fly before this newsletter reaches you. It looks like Oshkosh 77 may be a big year for the VariEze. The coming two or three months should see the first flights of a couple of VariViggens as well.

NEWSLETTER BACK ISSUES

Canard Pushers from 1 to 82

For those of your who are new readers of the "Canard Pusher" and wonder what has transpired in the past, there are now a grand total of eleven issues in print. The first six are concerned with the VariViggen exclusively. Issues seven through eleven contain VariEze and VariViggen information. If you are going to build a VariViggen you will need all eleven issues to update your plans. If you are a VariEze builder you need this issue (#11) and the October 1976 issue (#10) for plans update. If you have very recently purchased plans (after February 1, 1977) a yellow sheet of changes may be bound into your manufacturing manual. If you have the yellow change sheet included, you only need newsletter #11 and on, to keep your plans current. If you sell your plans to someone else, please pass this information along with the plans.

FOREIGN BUILDERS

A package of VariEze engineering documentation has been mailed to the regulating governmental agencies of the countries listed below as an aid to homebuilders seeking permission to build. If your country is not listed and documentation is required to obtain permission to build the VariEze, have the cognizant office in your equivalent to our F.A.A. contact us on their stationery requesting a copy. Documentation has already been sent to the following nations.

Australia
Canada
Republic of South Africa
West Germany (BRD)
Belgium
Great Britain
Iceland
France

VARIEZE LANDING BRAKE SUCCESSFUL

A drag device has been developed on N4EZ to improve its previously poor short-field performance. The landing drag device was developed because the VariEze had to be approached at a low flight-path angle and used excessive runway in the flare due to its slow deceleration.

The landing brake is not a speed brake for high speed deceleration. It automatically closes above ninty-five knots to prevent overstress. As you can see in the photo, it is a very large belly-board positioned to avoid any pitch trim change. It hinges at a position just aft of the front seat bulkhead. A spring snubs it up in the closed position and provides sufficient down load in the open position that the pilot can deploy the brake with only a ten-pound force on the handle. The landing brake handle is located on the left console. The handle is immediately aft of the throttle with the speed brake closed and moves up and aft to open. In the open position the handle interferes with the pilot's arm enough to remind him that it's down, so he doesn't forget it for takeoff. Climb performance is adequate with it down, but engine cooling would suffer. There are no locks on the handle. The pilot merely moves the handle and the brake remains in the selected position (open or closed).

Now for the good news. The landing brake makes a dramatic improvement in the airplanes landing performance. Approach angles as high as seven and one-half degrees are possible with the engine at idle (about like a

Cessna 150 with one-half flaps). Forward visibility is improved because the approach can be flown faster (eighty to eighty-five knots) without severely compromising landing distance. Speed bleed-off in the flare is relatively rapid, similar to most lightplanes. Touch down scatter is considerably less than without the brake. Thus, it is much easier to "put it down on the numbers." VariEzes were previously restricted to runways greater than 2400 feet. The landing brake allows a pilot with appropriate proficiency to routinely use airports with runways less than 1800 feet.

The speed brake results in a mild buffet, similar to that with full flaps in some other lightplanes. There is no pitch, roll, or yaw trim due to brake deployment. Other than the noticeable buffet, the stall characteristics are not changed. The airplane is easier to fly the approach and to land with the speed brake deployed.

While the brake does improve the short field performance we still strongly recommend that you adhere to the field length restrictions in the owner's manual for your initial testing.

We are planning to prepare drawings for the speed brake and should have them completed before newsletter twelve. If you want to install a landing brake in your VariEze do not change anything in Section I. The brake is just as easy to install as a retrofit, as it is during initial construction. Please do not ask for the drawings before newsletter twelve; they will be available at that time.

VARIEZE PROPELLER EXTENSIONS
Now that Section IIA is out, we have received a number of requests for a recommended source of prop extensions. Suitable extensions are available from Ken Brock Manufacturing, Ted's Custom Props (9917 Airport Way, Snohomish, Wa. 98290), and Bill Cassidy (4652 Montview Blvd., Denver, Co. 80207). Contact them for details.

We mentioned earlier that we had used the standard Cessna 150 extension. We understand that Cessna has a newer extension out now and that it isn't suitable for a wooden prop. A wooden prop must be very accurately centered using a centering hole in the prop which mates with a centering boss on the extension or engine drive flange. The drive lugs and mounting bolts are not suitable for centering the prop. The newer Cessna extensions may also be short on surface area against the prop hub for use with wood props. We modified the older Cessna extension by adding a centering boss to it. If you have any questions about using an extension, call your prop manufacturer for his opinion.

The insert that we used to adapt the older solid type of Cessna extension looks like this: **SKETCHES OMITTED**

This adaption is for a flanged crankshaft. Anyone using a tapered shaft (S.A.E.O) should specify this when ordering an extension, since these engines require a different part.

VARIEZE ENGINES
The Continental 0-200A installed in N4EZ has 200 hours on it now and the crankshaft end-play measures exactly what it did on installation (.0105). We continue to believe that there will be no problem with the

A-model engine installed on the VariEze. The total maintenance to date on the 0-200 has been an oil change each fifty hours.

Two engines under consideration for an eventual Section IIC are being installed in VariEze airframes now. One builder is working on a stripped Lycoming 0-235 installation and another group has a Honda Civic installation ready for initial testing. No data is yet available on the success of either installation but we are hopeful of good results from one or both within the year. Let's hope that both of these groups have the resources to pursue their projects to a successful completion, but please don't bug us with requests for advance information on their progress!

We understand that the Revmaster folks are continuing their development work on a good VW installation for the VariEze but we haven't heard from them lately.

VARIEZE CONSTRUCTION HINTS

Every time we turn around it seems like we discover a little better, faster, or easier way to build a VariEze. The hints in this section are a collection from our seminars and from the inputs you builders have made. Some of the information is new and some is clarification of items people seem to have trouble with.

Basic Glass Working Techniques

Paint Roller - Tracy Saylor has suggested using a thin paint roller, cut to a three inch width to help wet out the cloth. We've been using one and are pleased with the results. Do not dip the roller in epoxy; use your brush to apply epoxy to the general area where required, then use the roller to wet out the cloth and distribute the epoxy evenly over the surface. The three-inch roller width is great for working down in the canard spar trough and other tight spots. Rollers can be cleaned in acetone or M.E.K. a time or two before you throw them away.

Bristle Stipple Roller - The giant pipe cleaner supplied by Aircraft Spruce and Wicks is a stipple roller. Those of you who haven't figured out how to use it on your own can look at the cartoon "wetin' it out" on page 3-17 and on page 18-2 in the photos. You build your own handle from some aluminum or steel sheet scraps.

Dry Lay-Ups - The finished parts that we have seen at seminars have generally been very good. The general tendency, however, has been to make parts a little dry. You guys are taking our emphasis on stippling and "not wet" a bit too zealously. Be sure your lay-ups are not too dry (with small white flecks of unwetted glass visible). When you think you are finished with a lay up, DON'T QUIT. Take your portable light and very carefully inspect the lay-up while it's still wet. A cured lay-up that is too dry must be rejected. Also, before you leave a lay-up to let it cure, get a second opinion. Have the wife come out and inspect it while it's still wet and fixable.

The structural quality control criteria in section I, section V, and newsletter 10 are maximum allowable defects. Anything worse and the

part must be repaired or rejected. Your structural parts in general should be much better than these criteria.

Do not assume that the plans do all your thinking for you. Check all sections, photos, drawings, etc., on each step. Be sure you have no bumps, depressions, or joggles on the surfaces in a spanwise direction on all structural parts.

We have been informed of two instances where epoxy has been found to be too viscous - one or two bottles in a given shipment being more viscous than the others. If your epoxy is thick like honey, return it to the distributor for replacement. Also, if any separation occurs in your hardener, shake well and warm the bottle (80 degrees); if any settling still occurs, return the hardener for replacement.

Lighting - We've found that the source of many problems has been poor lighting in the shop area. If you can't see well you can't do good work. A lot of generally well done parts have bubbles, dry areas, or wrinkles just because the builder didn't have good enough light to see them!

Flox Corners - Paint a light coat of pure epoxy inside before troweling in the flox. This improves the bond of the flox with the dry glass.

Slurry - Don't be skimpy with the micro slurry over foam before you lay up glass. An incompletely slurried foam surface will allow little pockets of air to remain between the first ply of glass and the foam. The porous glass/foam interface can result in a premature breakdown of the foam-to-glass bond, and reduced surface durability. This is particularly important with urethane foam.

Micro Fills - If you fill a foam ding or nail hole with dry micro before laying glass over the surface, the micro will be soft during the lay-up and hard stippling will push the dry micro out of position. Avoid stippling ambitiously directly over a fresh micro fill with your brush. The paint roller is useful in these areas because it will bridge across the fill area and help wet the cloth without disturbing the micro.

Shop Temperature - In Section I we gave a maximum temperature range for glass laminating of sixty-five to ninty-five degrees Fahrenheit. The desirable shop temperature is about seventy-five degrees Fahrenheit. It's winter and a lot of you are trying to work at the minimum temperature of sixty-five degrees Fahrenheit. A major lay-up done at sixty-five degrees can take nearly twice as long to do as it does at seventy-five degrees Fahrenheit, because of the additional stippling time required to wet out the cloth.

"Peel Ply" - The bulk of sanding on cured glass surfaces in preparation for glass-to-glass bonding can be avoided by using a "peel" ply. A peel ply is a layer of dacron fabric which is laminated into a lay-up as though it were simply an extra ply of glass. The peel coat wets out with epoxy just like the glass cloth does and cures along with the rest of the lay-up. The dacron peel ply doesn't adhere structurally to the glass and can be peeled away from the cured glass very easily (about like masking tape). The removal of the peel ply leaves a surface which is ready for glass-to-glass bonding without sanding. Here's an example

of how to use the peel ply: in Chapter eight, Step six, lay up the top side pads, sparcap, and shear web just as the instructions on page 8-6 describe, then laminate one ply of dacron cloth over the front and back faces (shear web) of the spar. Let the assembly cure. When you are ready to lay up the bottom side, simply peel the dacron ply off on the fore and aft faces, leaving a surface which is ready for bonding. The peel ply is never left in the finished part; it is always removed as preparation for the next lay-up.

The peel ply can be used handily on the canard shear-web, leading and trailing edge glass lap joints of all aerofoil surfaces, wing shear web, center section spar, and wing tip/winglet root skins. The material for use as peel ply is 2.7 ounce/yard dacron polyester fabric. Both Wicks and Aircraft Spruce have the material or you may find Stits Polyfiber D-103 available at your local aircraft recovering shop. The dacron material is available in yardage and in conveniently-sized tapes.

Foam Core Assembly

Joining Foam Blocks - First paint a thin coat of epoxy (no micro) on the joining foam surfaces. Second, trowel a wedge of dry micro on the center of one surface. Third, squeeze the joining surfaces together, wiggling them back and forth, to obtain a thin micro joint less than one-sixteenth-inch thick. It is desirable to have the micro low in the joint about three-eights to one-half inch (not to get squeeze-out). The low joint is filled with micro before glass is laid over the joint, allowing a wet bond between the micro and the glass. You will occasionally get some squeeze-out even trying not to, so just wipe the joint low with a mixing stick. Do not try to fill large voids with micro; you are taking a chance of getting exotherm damage. If you have a void larger than about 0.1 inch, fill it with a sliver of foam with micro on each side, rather than solid micro.

Alignment - If your foam core is cockeyed when you glass it, your airplane will be cockeyed too and probably fly that way. Get your foam cores assembled correctly. Use lots of nails to hold it straight while the micro cures. Check the depth of the spar notch and be sure that it's correct, top and bottom. Wing and canard foam cores should be assembled vertically as shown in the photos on page 6-6, nailed together firmly, and the depth of both spar notches checked before placing it in the jig blocks.

Weight - Micro is heavy and costs a lot more than foam scraps. Use a foam block to fill the big gap around the wing fitting nuts instead of the large micro fill shown on page 6-18 (inside the wing root). Even a rough fitting foam block will be much lighter. The interior foam face is given a one-ply BID protective covering.

General Hints/Clarifications Page 6-5 - The seventh ply of BID, fifty-three inches by twelve inches, is used for the wing root and mid spar ribs shown on the top of page 6-6, same step.

Wing Jig Blocks - Jig block "F" may need to be shimmed slightly to get the leading and trailing edges straight. Jig block "E" must be notched slightly to allow the wing fitting to nest properly.

Wings - Above all else, both wings must have the same twist and be set at the same incidence.

Brakes - Use Rosenhan master cylinders with Rosenhan brakes. The Gerdes or Rosenhan master cylinders can be used with Cleveland brakes. Do not match Cleveland or Gerdes master cylinders with Rosenhan brakes.

--Ed Hamlin reports that a Dremel #428 wire brush works beautifully for cleaning the residual foam and micro off of the canard, wing and winglet trailing edge overlaps in preparation for the top skin lay-ups.

--Builders wishing to use enamel or acrylic enamels may want to use Dupont 3011S enamel primer surfacer in place of the 70S lacquer primer surfacer. 3011S provides the same ultra violet barrier that 70S does (see section V).

--Be sure you have at least the overlap shown at the trailing edge for the top and bottom skins (0.4 inch on canard; 0.5 inch on wing and winglet). Be sure the overlap area is sanded well before top skin layup.

--Do not pressure-check the fuel tanks before installation of the outside skin, unless a low pressure (five hundred feet) is used. (Page 21-6).

--Elevons must be free of friction.

--Use a lubricant on the mating surfaces of the wing fittings and NG13 guides (Lubriplate, Molycoat or eq.).

--When mounting NG6 and NG15 to NG1, layup a two-ply BID patch between NG1 and the castings. Mount wet, with flox filling any voids.

--One builder moved his canopy forward two inches from the position shown on the plans to obtain more room for the pilot to lean forward in flight. (This is being done on Jirans prefab canopy frames.

--The NG6 casting supplied by Ken Brock is narrower than is shown on page 17-3, a change dictated by production tooling. Nothing is changed because of this; Brock is simply including two spacers to center NG6 in the airplane. NG7 should be 2.75 inches long.

--Don't be concerned if you find it necessary to grind some of the MG-1 landing gear leg away to set the proper toe-in. A little grinding is normal and up to one-fourth inch of the gear leg thickness can be removed without structural concern. The mains should have about one degree toe-in.

--The basic bill of materials doesn't include the eight AN4-15A bolts and MS21042-4 nuts required for installation of the Cleveland axles. We have now flown Cleveland brakes and are happy to confirm that they provide excellent braking effectiveness.

--The sketch at the top of page 18-2 has confused some builders. The seventeen-inch dimension is correct, and the gear leg sweeps forward as the three-view drawing on the back cover shows.

Hot Wire Controls - The simple wire-and-nails voltage control shown in newsletter #10 can be hazardous if improperly used. Do not use it if the floor is damp. And, be sure you have the correct end to ground. Careless operation could ruin your whole day!

The schematic shown below is another possibility for a good hot wire control. This one cannot shock you. **SKETCH OMITTED**

URETHANE FOAM DETERIORATION

Newsletter #10 reported on the urethane deterioration in the fuselage side on N4EZ and its repair. Since then airplane has had some rugged use including large temperature cycles. Recent inspection revealed that there has been no further deterioration. The repair is sound and there appears to be no cause for concern in this area.

N4EZ has had some urethane foam damage in another area. This is in the center of the fuselage floor from F.S. 80 to F.S. 95. As shown in the sketch this occurs only in the center where the floor surface is convex and where high concentrated loads are applied when a heavy backseater with hard soled shoes puts all his weight in one local area. The glass skin is not damaged but the foam is locally deteriorated under the glass. This was repaired by gluing a piece of nine-millimeter, six-pound PVC (red) foam on top with wet micro. The PVC is heat formed (three hundred degree oven or heat gun) to hold its shape and weighted in place. After cure, layup two plies BID over the PVC. This provides a very durable surface. The PVC piece is fifteen inches long and ten inches wide. It is recommended that you install this piece in your airplane to prevent damage. It is not required over the entire floor. The concave surfaces spread the load out and no damage occurs. If you have no six-pound PVC you can substitute balsa wood. **SKETCHES OMITTED**

VARIEZES HAVE MODERN CABIN HEAT SYSTEM

Those of you northern die-hards that still think the VariEze needs an exhaust-powered cabin heat system should go to the library and look up a book on solar heating systems. You will find that the VariEze fuselage is strikingly similar to a well-designed solar heat collecter--a urethane foam box, diffused surfaces inside, glazed on top with plexiglass. It is well ventilated for summer cooling but with the vent closed and a good canopy seal you can maintain seventy degrees Fahrenheit inside temperature, with an outside air temperature of ten degrees Fahrenheit! This heating system, of course, does not work at night, but good fighter pilots fly in the daytime and love at night.

QUESTIONS/ANSWERS

We continue to be asked questions about our opinion of systems or configurations different from those who have tested and recommend on the Viggen or Eze. Please remember that if we haven't built or tested a given aerodynamic configuration, engine installation, avionics system, etc., our answer must be that we "don't know." We will continue to support builders by helping them with any problems or

questions they have, relative to the basic airplane and systems as shown on our plans, but we cannot serve as a clearing house or consulting service for items different from those in which we are familiar, particularly different engine systems and avionics.

Remember, your letters can be promptly answered only if you provide a self-addressed, stamped envelope. If the S.A.S.E. is not included, we will answer your question in the next newsletter.

Q. I want to keep my VariEze as simple as possible and plan to eliminate the roll and yaw trim. Is ground-adjustable trim okay?
A. We appreciate your desire to keep it simple, but do not eliminate inflight trim. The VariEze is a real pleasure fly in-trim or hands-off (which requires three-axis trim) but is quite a nuisance when out of trim, particularly in roll. We consider the ability to adjust roll trim with major power changes a mandatory item.

Q. I haven't been able to get to one of the demos--when can I see the VariEze?
A. We have not been showing it on an individual basis since this requires locking up, traveling a mile and opening the T-hangar. The response has been so great that this would take all our time. This situation will be resolved by about the end of February since we will be moving into a hangar on the flight line so you can come in anytime and inspect the airplane.

Q. I don't want to build an airplane that is still undergoing changes. When are you going to freeze the design and stop making changes?
A. We are more interested in the research and development aspects of aircraft than in marketing/promotion. Trying different things to improve an airplane is where our expertise lies. We expect to continue to use the VariEze as a research test bed for a long time, experimenting with several interesting concepts and may be making changes ten years from now.

Q. I'm just about ready to make the first flight in my VariEze. What words of wisdom do you have to the "about to be" test pilot?
A. The best thing we can tell you is to read your owners manual very carefully and follow exactly all the information and limitations shown. The VariEze is a very stable airplane but has lower stick forces than the average lightplane. So, get some time in a Yankee or other "sensitive" airplane. Also, remember that your rudders are a more powerful roll control than the elevons, and if your new airplane is crooked you may need rudder to keep things upright. In fact, you should fly the airplane primarily with rudder, since if there is anything that takes getting used to on the VariEze it is the tendency to input pitch when trying to use only aileron. So, if you use the stick only for pitch and the rudder to turn, things will seem easier, particularly if your proficiency is not good. Also, remember to keep the airplane in trim by adjusting pitch, roll and yaw trim. When in trim the airplane will hold speed and level flight even in turbulence without pilot effort. This will make your initial flights much more comfortable than fighting an out-of-trim condition. On final approach,

set up roll and yaw trim for coordinated level flight, then the rest of the landing is VariEze indeed.

Too many people do a professional job of building their airplane then lose everything because they do a non-professional job of flight testing. If something is not quite right--fix it before you fly. Be sure your pilot proficiency is sharp and current.

IMPROVED VARIEZE FUEL SYSTEM

We have recently tested a new fuel system in N4EZ that offers some significant advantages over that currently shown in Section IIA of the plans. The following schematic shows the system. Note that the pump and the small header tank on the vacuum pump pad are both eliminated. **SKETCH OMITTED**

The fuselage tank is filled when the aircraft is fueled-- it has its own cap (same cap as on wings). The fuel system is operated as follows: The fuselage tank is normally used only for starting the engine with the nose down. The wings are selected after the nose is up and the pilot gets in. If the flight is planned so that the descent is done with less than two gallons in each wing, the pilot selects the fuselage tank for the descent and landing. Regardless of the flight planning, the pilot can use all the wing fuel in level flight or climb (There is less than 0.1 gallon unusable). He can use all but one gallon per wing in a normal descent and all but two gallons per wing in a steep descent. All fuselage fuel can be used in any attitude.

Addition of the selectable fuselage tank gives the pilot a much more accurate indication of his last few gallons fuel, thus increasing range and decreasing his concern of exact usable fuel state when fuel is low. It also gives redundant backup for things like fuel vent blockage, loss of fuel cap, etc. It does require fuel management though, but not more so than with the pump. The fuel selector is designed to mildly interfere with the pilots wrist to remind him not to take off with the fuselage selected, thus depleting descent fuel first.

The selector handle is positioned left for wings, up for fuselage, and right for off. The selector valve is operated directly with a torque tube running forward. The torque tube is easy to install even with the side consoles in place. The torque tube has a mild curve which positions it against the fuselage side from F.S. 70 to F.S. 90, thus it does not interfere with the suitcase. Route holes in bulkheads as required

The system low point is provided with a drain adjacent to the selector valve. The drain is installed by drilling a five-sixteenth inch hole in the AN910-2D coupling and tapping with a 1/8-27 N.P.T. tapered pipe tap.

The fuselage tank is located forward of the firewall over the wing spar. The fuselage tank in N4EZ (see photo) is fiberglass. The front and back sides are three-eight inch urethane (or PVC) foam with one ply BID on the inside. The top, bottom-and sides are two plies BID, laid up flat like the practice piece on page 3-13 of Section I. The pieces are assembled with epoxy, then the corners are rounded and two plies BID are laid over all the outside (overly wet layup to avoid leaks). The

sight gauge, vent, cap, strainer, and fuel outlet are made similar to the wing tanks.

The tank was bonded to the spar on the bottom with wet micro and a block of six-pound PVC foam and bonded to the roof at the top (around fuel cap) with a ring of PVC and wet micro. While this looks like it will work okay, it's probably a better idea to fabricate some metal straps and bolt the tank to the firewall. If your tank interferes with the canopy brace bar, move the bar forward. A welded aluminum tank could be substituted if desired, or better yet, maybe we can talk Ken Brock into making a rotary-molded one like the original header tank.

One builder has told us that the Bendix-Strongberg carburetor will function satisfactorily with a very low fuel head and should work well with this new fuel system. We have not tested the Bendix carburetor so we have to leave verification of this up to you.

Some of you may not like the idea of a fuel tank within the confines of the cockpit. This is, however, a fairly common practice for many lightplanes. We feel that the advantages of more reliable fuel flow near zero fuel level, outweighs any disadvantages and thus recommend that you install this new system in your VariEze. Detail drawings on page 6.

Make the following changes to your Owners Manual, Section IV.

Check List	Engine start--add "select fuselage tank" before "mixture rich." Before takeoff--add "wings" after "valve on. Descent--omit "if low fuel refill header tank each six minutes." Add "select fuselage tank if wings are less than two gallons each."

CP11, Page 5

NUMEROUS SKETCHES, TEXT AND TABLES OF NEW VARIEZE FUEL SYSTEM OMITTED

CP10, Page 6

OWNERS MANUAL CHANGES, CONT:

Page seven- Fuel System	Omit entire section. Add "The fuel system consists of two wing tanks and a small fuselage tank, all equipped with visual sight gauges. A three-way selector is located on the pilot's right console. The selector is positioned left to select wing fuel, up to select fuselage fuel, and right to off. The wings hold about twenty-four gallons total, all is usable for climb or level flight. One to two gallons per

	tank are not usable for steep descents. The fuselage tank holds about 2.5 gallons, all is usable in all normal attitudes. Drains are provided at the wing tanks and at the fuel valve (system low point). The wing tanks are vented together to maintain equal tank fuel levels."
Page fifteen-Descent	Omit last paragraph. Add "If a long normal descent is made with less than one gallon of fuel in each wing tank, fuel starvation may occur. Fuel flow can be regained by selecting the fuselage tank or by reducing descent angle. Starvation can occur during long steep descents with two gallons per wing tank. Because of this possibility, the fuselage tank should be selected for all descents and landings, with less than two gallons per wing tank.
Page thirty-two-Appendix I	Omit sentence on safeting fuel valve. Under weight and balance add "check aft cg limit with full fuselage fuel."
Page twenty-two-Engine Failure	Omit all of the top paragraph after "fuel starvation." Add "select fuselage tank. If wing fuel starvation occurred during descent, the wings may have one to two gallons of fuel that is still usable during level flight or climb."

VARIEZE PLANS CHANGES

We are still getting a large volume of questions from builders over the phone and by mail that are answered in the plans or in newsletter #10. Read everything thoroughly before you start bugging us! Transcribe all plans changes into your plans--don't try to memorize them.

Page Number	Changes
5-6	A few builders have had problems getting enough elevon travel. We now recommend that you modify the elevon location template--jig block "B" as shown in the sketch. This will give enough travel even if your canard is not quite straight. **SKETCH OMITTED**
6-21	The Radio Shack switch is not a spring-to-center type. A Micro switch #8A-2041 should be used.
7-1	The four UND skin plies are considerably oversize as shown (fifty-five inches by thirty inches) and may be reduced to fifty inches long and twenty inches wide at root.
17-3	1.15" should be 1.25" (NG6)
7-2	The middle sketch at the top of the

	page should look like this. **SKETCH OMITTED** Use the drawing at the bottom of 7-2 to cut the winglet planform, not the info at the top of page 7-1.
8-7	Add these instructions to the end of Step 8: Before mounting the fuel tanks, round the edges of the wing fitting plates and layup a three-inch strip of UND wrapped twice around the centersection spar as shown. This provides a glass surface for the cowling lip layup (see Section IIA), stiffens the spar end, and safeties the wing fitting screws. **SKETCHES OMITTED**
15-1	The two 5.4 by 2.7 inch pieces of medium density PVC foam should be 5.4 by 3.2 rough to allow for matching the contour of the seat back. **SKETCH OMITTED**
17-5,2-2 & 2-3	(One each) AN5-37A bolt should be AN5-40A. The 37A is adequate if your pad was not laid on too wet. (Two each) AN4-36A bolts should be AN4-40A. (Eight each) AN509-10R-9 should be AN509-10R-14.
20-2	#38 drill should be #42
21-6	3000 feet should be 1500 feet.
22-8	You may want longer canopy hinge screws than the 509-10R-6's shown if your canopy frame is thicker than the prototype N4EZ. Get as much grip as possible.
22-7	Blank should read "See page 25-1."
22-8	AN509-10R-12 should be AN509-10R-10.
Section IV Owners Manual Page 48	Add the following notes: Subtract one hundred feet from the ground roll if landing brake is used. Also: Subtract four hundred feet from the landing distance over a fifty foot obstacle if the landing brake is used.
Section IIA Page 5	B.L. of lower mount points should be B.L. 5.25, not 5.5.
Section IIA Page 10	All three weatherhead fittings should be drilled out to an inside diameter of .281 (9/32) to increase fuel flow. Also: AN42B-4 should be AN42-7A. (These do not apply to the new fuel system).
Section IIA Page 13	Continental #53627 should be #530627. Also: AN844 should be AN884.

VARIEZE PLANS CHANGES, CONT.

Canard Pusher #10	K1000-3 should be K1000-4.
Page 5	
Page 6	Top right-hand corner, 10-5 should be 10-3.
Section IIA	Omit Step four and Step twelve. Modify Step five as shown in this newsletter. Omit photo of valve on page twenty. Substitute fuel system shown in this newsletter. Do the fuel flow checks in Step twelve for the wing and fuselage fuel.

STRUCTURAL TESTING

We have conducted another VariEze static load test since newsletter 10. A homebuilder brought his canard to our shop to show the problems he had in construction. He knew that the canard did not meet the quality control criteria (a large depression in the spar at B.L.42, many dry areas, and inadequate skin overlap at the trailing edge) so he had rejected it. He left the canard with us so we could use it to show others how not to do the work. We decided to load it to destruction to determine its actual strength.

The canard was mounted in a fixture (see photo) that mounted it by the lift tabs and trailing-edge pins similar to the normal mounting on a VariEze fuselage. Test results showed that the strength of the canard was considerably reduced due to the construction errors, but the canard was still strong enough to meet FAR 23 (failure above 150% of limit). Failure occurred at the depression in the top spar. **SKETCH OMITTED**

Another builder showed up at a workshop with a test fixture he had constructed. His eyeball engineering had told him that the canard lift tab was too weak, so he built a 2-ft span of a canard complete with lift tab built to the plans. The canard section was supported at the tips and he applied 2200 lb to the single lift tab - no failure occurred. Needless to say he is no longer worried about lift tab strength!

HAM RADIO OPERATORS

Ivan Whitehouse (Goldendale, Washington), K7ATX, reports about twelve hams have joined the "VariEze" net. He reports poor luck with the Tuesday evening net and says that they will try Thursdays at seven a.m. on 3900 Khz.

ED HAMLIN WANTS YOU!

Ed Hamlin (8377 Seeno Ave, Roseville Ca 95678) was the host of the Sacramento VariEze seminar. He is organizing a "squadron" - a club for EZ builders in central/northern Calif. Purpose is to work together to help each other with building and flying problems and to promote Sport Aviation. If you are interested, send him a S.A.S.E. for his newsletter. Ed has done real first-class work on his half-completed VariEze.

NEW FUEL SYSTEM IN N4EZ - SEE PAGE 5 AND 6. **PHOTOS OMITTED**

Minnesota already has a VariEze club.

VARI EZE DISTRIBUTOR STATUS

JIRAN - Producing 4 main gear per day and 3 cowlings. Current backlog approximately 9 weeks.

COWLEY - Shipment within two weeks

BROCK - Most items available for immediate shipment. Wing fittings, engine mounts, and nose gear castings backlogged about 2 months.

AIRCRAFT SPRUCE & WICKS ORGAN - most items avail. immediately; a few long lead items make full shipset deliveries about 1 to 2 months. On the average, two complete shipsets per day have been delivered to homebuilders in the first 5 months of the VariEze program. This is an excellent record, unsurpassed by any other homebuilt kit supplier.

THIS IS FROM A RECENT PRESS RELEASE FROM NASA!
COMPOSITE MATERIALS.
During the coming fiscal year NASA plans on intensive effort to reduce the weight and labor-intensive areas on today's production aircraft, with particular emphasis on composite materials (plastics, etc.). At this point all agree that composite materials are hopelessly expensive for aircraft use - both in actual dollars and also because (again) they raise the specter of enormous product liability insurance cost. NASA is coordinating its research with that of others in the "consumer item" fields (principally auto manufacturers) to try to bring costs down and technology up. NASA admits there is much still unknown and expects that it will be a 6-7 year effort before results appear in the tie-down areas.

The next generation of business jet may have winglets too. The new Gulfstream III will make its first flight in 1978. **PHOTO OMITTED**

VARIEZE BUILDER REPORTS

You guys don't write much but we do get a few pictures.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Nat Puffer's canard, elevons and center section foam core.

Cy Mehling's (Doylestown, Pennsylvania) airplane as of early December. Photo taken 3 months after receipt of kit.

Tom Kuffel's (Anchorage, Alaska) first knife trim... at three a.m.! That's loyalty!

Nat Puffer's wings and center section spar completed and aligned. Anybody recognize the thing hanging from the roof?

Puffer's rudders ready for the bottom rib.

K. Kuffel - the First hot wire cut.

Dr. Wagner's fuel tank going together.

Hans Steinhoff (Goleta, California) has the right idea on weight--his wings and canard had to be tied down! (Well... it's a nice idea anyway.)

Dr. John Wagner shaping his canopy frame.

A.G. Ebel's airplane after four months work. December 8, 1976.

VariEze S/N 124's canard doubling as a park bench. This is not recommended. That much weight concentrated on a sharp saw horse can damage the structure. If you do this, place a foam block on the sawhorse first.

Cy Mehling's airplane in October.

WHO'S BUILDING The best way to find VariViggen or VariEze builders in your area, is to attend your local EAA meeting and ask who is building. If you're building a VariViggen or VariEze, clip out the card below, fill in, and mail to EAA, PO Bx 229, Hales Corners, Wi. 53130, attn: A/C Records Dept

CP11, Page 9

VARI EZE REFERENCE DIMENSIONS
This sketch gives a summary of fuselage stations and butt lines which are easily checked on the completed airplane. All of this information is in the plans but some of it you have to hunt for. The points marked by the asterisk (*) should be checked during final weight and balance and the real values recorded in your airframe log (Drop plumb-bob to lines on floor). **SKETCHES OMITTED**

VARIVIGGEN PLANS CHANGES

Page	Change
VariViggen Plans Page 5	Top of WS 28 should be 3.1 not 3.0 as shown.
SP Wing Plans Page 14	AA-3 should be two required-1/4 inch 2024-T3 aluminum 1.0 by 12.4.
SP Wing Plans Page 13	Under wood--two pieces 1.0 by 1.5 by 24 should be four pieces.

VARIVIGGEN BUILDER REPORTS

Ken Guscott, S/N 129, reports that he has the fuselage and inboard wing complete and ready for cover. Ken says that he's disappointed that more VariViggen builders haven't been sending information in for the newsletter. We agree. What are you guys up to?!

Jim Cavis reports that his airplane is ready for first flight, paint and all. He is mounting the canopy plexiglass now and as soon as he finishes we'll have a genuine flight report for you to read. Jim has the standard wing plan form on his airplane but built it from foam and glass. He plans to fly it in standard configuration and later add winglets. This should be interesting.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

The Stow, Mass. construction seminar. Photos courtesy of Charles Douette.

Cuscott's fuselage and wing ready for skins

Ken Guscott's chain drive nose gear retraction mechanism.

IMPORTANT ADDITION TO NEWSLETTER 11 - SIMPLE SPOILERS AID ROLL CONTROL

AFTER NEWSLETTER 11 had gone to press we invited Peter Garrison, an aviation writer for "Flying" magazine, to fly N4EZ. He flew it several times and was pleased with the improvements due to the speed brake; however, he expressed concern that the airplane may be a "handful" for a low-proficiency pilot, due to its relatively sluggish roll rate and due to a tendency to pitch nose-down with aileron inputs. These comments caused us concern, and a little surprise, since we hadn't really been aware of a significant pitch change with aileron. We flew the airplane again and noted that, yes, indeed there is an objectionable nose-down pitch change, but only for large aileron inputs. Apparently we generally use only small aileron inputs and a lot of rudder when needed for high roll rates and, being accustomed to flying the airplane in this manner, we were not of the opinion that the airplane was difficult to maneuver. Trying to put ourselves in the place of a low-proficiency pilot on his first VariEze flight where he may be flying an airplane out-of-trim and might be unable to roll at all, if he is using a lot of opposite rudder, led to the conclusion that Peter was right; the airplane does need to be improved to make it safe for some pilots.

We have always been reluctant to put rear-wing ailerons on the VariEze due to the control system complexity, the need to hookup controls for wing removal, and the addition of a new possible flutter mode. What we needed was some additional roll rate, a slight nose-up pitch change with roll deflection, and perhaps some proverse yaw. We rigged up a small spoiler on the cowling just aft of the centersection spar, and found that its deflection almost exactly canceled the nose-down pitch and made the roll rate higher. Addition of this spoiler made the roll response more crisp and made the VariEze feel more like a conventional

airplane. It was a little hard for us to believe that this small spoiler, mounted that far inboard, was really making that much difference; so we invited Peter up again to fly our modification. He was skeptical because of the small size and placement of the spoilers, but after his flight, which included maneuvering at all speeds and several landings, he agreed that all pitch change due to roll was gone and that roll control was more like a conventional aircraft. When asked if the aircraft was safer for the low proficiency pilot, he replied, "Definitely." We agree, and are therefore recommending the simple spoiler system shown below as a mandatory addition to your VariEze.

The spoilers have a negligible effect on cruise speed. They are far enough from the leading edge to be included in the boundary layer. There are no changes to the current control system. The elevons still work normally; the spoilers are merely an addition. A bracket (CS18) is bolted on the stick using the existing bolt. Cables (in nyloflo conduits) are routed aft along the fuselage side (no interference with the suitcase) and through the centersection spar. These cables rotate tubes which directly deploy the flat-plate spoilers, through four slots in the top cowl. One light spring per spoiler holds them down against the cowl. CS18 is offset such that only a very minor slack exists in one cable when the opposite spoiler is fully deployed. The complete system was designed to be easily installed in a completed airplane. It was built and installed in N4EZ in one day. The front half of the pilot's armrest was removed for access and reinstalled with flox after spoiler installation. Note that the armrest side must be hollowed locally to provide clearance with CS18. No turnbuckles were used. The cable Nicopress sleeves were swaged as accurately as possible, then final adjustment was made by moving the CS19 block up and down. The spoilers are rigged to start moving up just as the stick moves away from neutral and to reach full deflection (about 50 degrees with no airload) at full roll control. Spoiler rigging is effected only slightly by fore-aft stick motion (pitch control). Be sure it's hooked up so the left spoiler deflects when the stick goes left (the cables cross under the rear armrest). The cables are routed on both sides of the front seatbelt attachment.

The spoilers are plates of .063 2024T3 aluminum. At neutral, they sit flat on top of the cowling. They are attached to a weldment with two AN525-10R6 screws per spoiler. Cowling removal requires removing the four screws, or the cowling can be slotted forward to allow removal without disturbing the spoilers. The weldment consists of 1/2-inch dia. steel tubes with pivots and brackets. The right side has two hinges: one at B.L.8.4R where the cable attaches and the other between the two spoiler mounting tabs (CS24's). The left side has three hinges: one between the CS24 tabs, one at B.L.131, and one at the cable attach point. Because of the spar dihedral, a universal joint is required at B.L.12L

Four hinge brackets (.063 alum formed angle) are bolted to the centersection spar (CS20 and three CS21). They are mounted wet with flox and the excess flox squeeze-out prevents rotation should the metal bond fail, thus only one mounting bolt is required. These brackets are drilled in last, with the entire assembly bolted together, to allow adjustment so the spoilers sit flat on top of the cowl.

A small steel spacer, the same as that used at the bottom of the rudder pedal (VECS13), is used at each of the five hinge points. The 1/4" OD spacer is clamped to the aluminum brackets by the AN3 bolts and the steel brackets rotate on them

One spring is used per spoiler. It is installed as shown using an AN100-3 thimble through one of the CS24 brackets. The spring is sewn to the thimble and to the bottom cowl flange with two loops of .041 safety wire. Adjust for a very light snub in the neutral position. The spring is a C-133 type (Century Spring Corp., L.A.). We found it at the local hardware store. You can substitute any spring with a spring rate of about two pounds per inch deflection. Do not substitute a heavy spring like a screen-door type.

Full-size patterns are shown, to be used to make the required brackets. When the brackets are welded to the tubes be sure to align them as shown. Install the Nyloflo conduits as follows: first sand their surface dull for bonding, string them into the airplane as shown. Bond them to the spar and armrest in the rear (flox/5-min); let cure. Pull them tight at the front to straighten them, tape to the side between FS65 and 95 and bond every eight inches with a blob of flox/5-min. Glue the forward block (CS19) to the side, floor, and armrest, potting the formed curve in the tube with a lot of 5-min/flox. CS19 is glued in last, so its vertical position can be adjusted to final-adjust cable rigging. With the Nyloflow tubes mounted straight, very little cable friction will exist. Do not use Nyloseal tube.

OWNERS MANUAL ADDITIONS

ADD THE FOLLOWING to page 7 of your owners manual: "small spoilers located on the centersection of the aft wing are used to augment the roll control."

INSERT the following to replace the landing gear speed data on page 17 of your Owners Manual- "Don't extend gear above 100 kt(115 mph) - at higher speeds the airloads make it hard to extend. Gear can be down or can be retracted at speeds up to 140 kt(163 mph)

ADDITIONAL NEW ITEMS

THE PLANS AND PREVIOUS newsletters indicated that it may be acceptable to use larger tires on the main gear of the VariEze. This may not be so. Cowley's VariEze has experienced a severe fore-aft resonance (vibration fore-aft) of the wheel when taxiing at a medium speed (about 15-20 mph). This may be due in part to a high spot or grabbing of the brake disc (his disc thickness was not uniform), but it may also be caused by resonance excited due to the larger (and heavier tire). This vibration at 20 mph is sometimes evident on N4EZ with the 3.40x3x5 tires but it is only mild and intermittent. It does not occur at higher or lower speeds. CHECK YOUR DISC THICKNESS!

One builder brought in a canard/elevon assembly in which he thought his elevon up-travel was only 21 deg, instead of the required 24 degrees. On closer inspection we found that the trailing edge of his canard was a bit high, making his elevon template read -3 degrees when the elevon was at zero, and thus his elevon travel was adequate (24 deg). If you suspect that your elevon degree template is giving the wrong

information, place jig block B, page 5-6 under your canard to line up zero elevon deflection, then check that the elevon degree template reads zero.

Peter Garrison landing N4EZ. Note new spoilers & landing brake.

THANK YOU FOR YOUR INTEREST IN THE VARIEZE TWO-PLACE SPORTPLANE

**PHOTOS OMITTED

THE STORY
For the last 12 months, we have refrained from promotional activities and marketing on the VariEze to concentrate totally on its development and setting up materials and components distribution. In this short time, we have 1. flown a full 350 flight-hour test program on two prototypes, one Continental and one VW-powered, 2. completed full structural qualification testing, 3. prepared a manual for the amateur builder to educate him in the structural materials and to guide him through construction, 4. set up a materials distribution system through established, competent distributors.

THE TEST PROGRAM
The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE RESULTS
The VariEze has superb flying qualities for its primary mission - comfortable travel. It has excellent hands-off stability even in turbulence. It is unusually safe at low speeds, can be flown with full aft stick (47 kt) without being susceptible to departure or spin, regardless of attitude or power. Performance is also superb - cruise

up to 200 mph and climb up to 1700 fpm at gross weight with the larger engines.

THE MISSION: PRACTICAL UTILITY
Although quite compact outside, the VariEze provides unusual comfort for up to 6-ft, 7-in, 210-lb pilots and 6-ft, 5-in, 220-lb passengers, plus two medium-size suitcases and four small baggage areas. The 24-gallon fuel load allows up to 1000-mile range at economy cruise. High altitude climb is excellent, for flying over turbulence, mountain ranges, and for satisfactory high-density altitude take offs.

THE DESIGN
The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic systems design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE STRUCTURE
New composite sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, longer life, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair.

THE HOMEBUILDER SUPPORT
The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations. Construction seminars are provided at RAF and elsewhere.

THE AVAILABLE HOMEBUILT
Established, competent distributors have stocked materials and components before the aircraft was marketed. All raw materials are now available plus many prefabricated items including canopy, landing gear, wing quick-disconnect fittings, cowling, all machined items, rudder pedals, engine mounts, suitcases and upholstery. If you choose to purchase all prefab parts, you can build your VariEze in about 500 man-hours - really!

VariEze documentation is available in five sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full-size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words! The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, A75, C85, C90, 0-200
SECTION IIB - VW engines (avail. Oct '76)

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system, avionics, landing and position lights, antennas, starter. Avail Sept. 76

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim. Avail Sept 76

	Gross Weight	1700 lb

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION

The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional

radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

The following are RAF-authorized distributors of materials and components. Items indicated have been developed under RAF approval and are recommended for VariViggen or VariEze aircraft. Contact the distributors at the address shown for his catalog and description of items. Indicate to him that you are a VariViggen or VariEze builder.

AIRCRAFT SPRUCE & SPECIALTY CO.
201 W. Truslow Ave.
Box 424
Fullerton, Ca. 92632
(714) 870-7551

OR

WICKS AIRCRAFT SUPPLY
1100 5th Street
Highland, Il. 62249
(618) 654-2191

Catalog cost $2 - Refundable at first order.
VariEze materials: epoxies, foams, fiberglass, filler materials, wood, metals, all hardware, specialized tools, skin barrier cream, seat belt/shoulder harness sets, wheels & brakes & custom upholstery/suitcases.
VariViggen materials: spruce kit, plywood kit, hardware, aluminum & fiberglass.

KEN BROCK MANUFACTURING
11852 Western Ave.
Stanton, Ca. 96080
(714) 898-4366

Catalog cost $1 - Refundable at first purchase.

VariEze prefabricated components: wing attach/quick disconnect assemblies, nose gear machined parts, control system components, fuel cap assemblies, welded engine mounts, welded stick assembly, welded rudder pedals, wheels & brakes.
VariViggen prefabricated components: all machined parts.

FRED JIRAN GLIDER REPAIR Write for brochure.
Building 6, Mojave Airport
Mojave, Ca. 93501
(805) 824-4558
VariEze prefabricated components: Molded S-glass main gear and nose gear struts, nose gear strut cover, nose gear box.

COWLEY ENTERPRISES Write for brochure.
P.O. Box 14
Santa Paula, Ca. 93060
(805) 525-5829
VariEze plexiglass canopy - Light bronze tint or clear.

H. C. COMMUNICATIONS Write for brochure.
Box 2047
Canoga Park, Ca. 91306
VariEze and VariViggen custom COM & NAV VHF antennas.

MONNETT EXPERIMENTAL AIRCRAFT, INC. Ask about VariViggen parts.
955 Grace St.
Elgin, Il. 60120
(312) 741-2223
VariEze - None
VariViggen - All molded fiberglass parts

GOUGEON BROTHERS Write for brochure.
706 Martin St.
Bay City, Mi. 48706
VariEze - None
VariViggen - 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS Contact him for list
4102 Twining
Riverside, Ca. 92509
VariEze - None
VariViggen - welded nose and main landing gear, 1-1/4" sq. steel tube.

BILL CAMPBELL (VariViggen builder) Contact him for list.
Box 253
Phelan, Ca. 92371
VariEze - None
VariViggen - Prefab brackets and fittings.

JESSE WRIGHT Contact him for list.
7221 S. Colorado Ct.
Littleton, Co. 80122
VariEze - none
VariViggen - prefab wood parts.

RAF ACTIVITY since the January Newsletter has included homebuilders support, construction workshops, more design work for NASA, and a move. The landing brake plans were completed in February--They are VariEze Section VI ($10, $11 overseas). They consist of five 18" x 24" sheets, all full-size drawings.

N4EZ, our VariEze homebuilt prototype, has been flying extensively over the last few months, including several long trips: 2000 miles for the Seattle workshop and nearly 3000 miles for the trip which included the Denver workshop. With the exception of some exhaust system cracks the airplane has been maintenance-free. Rides or checkouts have been given to several writers for "Flying" and "Aviation Consumer" magazines. Both plan articles soon. The VariEze has appeared in the following magazines lately: Plane and Pilot, Sport Planes, Sport Flying.

We have completed the last of our out-of-town composite construction workshops. These have proven to be very beneficial in disseminating the techniques of foam/glass construction. Cities in which the workshops were given are listed.

Oshkosh, Wis.
Highland, Ill.
Boston, Mass.
Van Nuys, Ca.
London, England
Paris, France
Austin, Tex.
Sacramento, Ca.
Atlanta, Ga.
Daytona Beach, Fla.
Snohomish, Wash.
Denver, Colo.
Anderson, Ind.
St. Paul, Minn.

We will also continue to have an occasional workshop and flight demo here at Mojave to assist builders with construction questions. The next scheduled demos at Mojave are noon to 2 p.m. on May 14 and on June 11. We also plan to fly N4EZ to the Watsonville Flyin May 28 and to the Chino Flyin April 30.

RAF has finally made the move to our new building on the flightline at Mojave and the airplanes are on display for visitors to stop by and see. Our regular office hours are 9 a.m. to 5 p.m. Wednesday through Saturday. We are closed to visitors Sunday, Monday, and Tuesday. Builders who have pressing problems may be able to catch us by phone on our closed days, but we may be out in the shop with epoxy up to our armpits, so try and call Wednesday through Saturday if you can.

The VariViggen homebuilt program has suffered a tragic beginning. Jim Cavis was seriously injured when an accident occurred during his initial tests. A report on this accident is included in this Newsletter.

The VariEze homebuilt program has started on a more positive note with four homebuilt airplanes now flying, and many more soon to fly. However, the VariEze record so far has not been good. One ended up being run through a snowbank removing all three gear and damaging the propeller when it veered off the runway on its first lift-off. Factors contributing to this included a gusty crosswind, one brake being stronger than the other due to a modification, and incorrect rigging of stops in the elevon control system. That airplane has been repaired and is now flying successfully. We are concerned about the safety of many of you who will be conducting your flight tests, since we have observed an almost appalling lack of good judgment of many who have and are doing test work. Some have had a complete disregard of the limitations and procedures in the Owners Manual and have overlooked important things like weight and balance, rigging of controls, etc. It seems unbelievable that anyone can spend so much work building an airplane, then be so sloppy when it comes to flying it. We have also noted that many builders are not familiar with many of the changes and additions in previous Newsletters. Be sure you copy all info from Newsletter #10, #11, and #12 completely into your plans and Owners Manual. A lot of this information is very important to you! A large portion of this newsletter is devoted to preaching and emphasizing the importance of quality control, careful conduct of your test program, and of following known limitations.

PHOTO OF WICK'S ORGAN COMPANY'S 101MW OMITTED

WEIGHT AND BALANCE AND INITIAL TESTING

The "lead" builders of both the VariViggen and the VariEze have begun to roll airplanes out of their garages and into hangars. RAF has been trying to keep tabs on these early birds and one alarming deficiency has been common to many: inadequate and inaccurate weight and balance. Now hear this all of you homebuilders: A slipshod weight and balance can kill you. The final weight and balance that you do on your airplane before flight testing begins is just as important as installing the wing attachment bolts. Use the weight and balance methods shown in your Owners Manuals!

A variation of "Murphy's Law" says that anything which can be misunderstood or ignored will be. Our weight and balance instructions are no exception. The first principle of a good weight and balance is to assume nothing. For example, you can't just assume that the nose and main gear stations are exactly as shown in the Owners Manual. It wouldn't be unusual to find that your main gear axle centerlines are as much as 0.5 inch or more off of the target of F.S. 108.0. A small

variation in gear location won't adversely affect the way your airplane flies, but it could lead you to believe that your center of gravity is forward (or aft) of its true location by quite a bit! The same principle applies to temporary ballast weights used to keep the airplanes nose firmly on the scales. You may find it more convenient to put your ballast weight in a different place than we show in the Owners Manual which is ok. But, when you make your calculations use the weight and fuselage station where you put the weight, and not our sample! Also do a weight and balance with the pilot in the airplane to check your calculations. Do not ignore the pilot weight placard in the Owners Manual. Be sure to check the dimensions shown on Page 10 of Newsletter #11 while you are checking gear reaction points.

Those builders who have convinced themselves that the world will stop turning if they don't have alternators, vacuum pumps, or starters on their airplanes will probably discover that the airplane is 1) overweight and 2) aft CG. If you discover this condition in your airplane you only have two options, you can remove the garbage that is causing the aft CG condition and help your weight at the same time, or you can add permanent ballast in the nose to get your CG where it belongs and make your overweight airplane even heavier. Not really much of a choice. If you can't part with your heavy accessories, you will be tempted to ballast just enough to get to the aft CG limit and you will be asking for trouble. We have established a limited "first flight" area on the allowable weight versus fuselage station graph in the Owners Manual. Your initial flight testing must begin within this area. The first flight box is expanded slowly and carefully as you and your airplane gain experience. You can't start your flying at the most aft (or most forward) CG that we recommended for fully proficient pilots and proven airplanes and expect to be safe! Don't compromise safety for the sake of a few unnecessary gadgets! Read and follow all information available to you. You are building a high performance airplane, not a toy. As you begin your testing be sure to give someone else besides the test pilot the responsibility to check that the airplane is ready, the Owners Manual procedures are being followed, and all limitations are met. He should also have the authority to make the "go", "no-go" decision and do the test planning. Test pilots have too much else to think about to be able to make correct decisions on these things.

Already we have seen people doing some really foolish things like flying without side consoles (the right one provides pitch stops!), doing initial testing in crosswinds of almost the full capability of the airplane (Owners Manual specifies zero for initial tests), testing on shorter runways than specified, etc. Unless you stay within recommended limits your chances of success are quite low.

When you get to the hangar with your new airplane take it easy, and do a thorough job of your initial systems checks, weight and balance, etc. This is not the time to hurry. "Homebuilderitis" effects us all and you will lust to see your airplane fly, fast! Don't talk yourself into doing something stupid just to please your ego; finish building the airplane before you try to fly it!

WEIGHT CONTROL

In view of the non-stop preaching done by RAF in our newsletters, plans, over the telephone, and in person, it is a little difficult for us to understand why some homebuilders are still happily ruining their airplanes by making them overweight. The VariEze is also VariSmall and it doesn't have a great deal of wing area. Adding a little weight to your airplane is like carrying another passenger in a Cessna 172!

The worst weight offenders are still the gadgeteers. Starters, generators, alternators, vacuum pumps, radios, gyro instruments, dual controls, etc., etc. One group of builders added dual 720-channel NAV/Coms, Dual VOR/ILS indicators, dual glide slopes, an annunciator panel, D.M.E., marker beacon, transponder, encoding altimeter, artificial horizon, directional gyro, rate of climb, turn and bank, starter wiring, nightlights, CHT and EGT, a 25-pound battery, and an alternator to power it all. Aside from the $14,000 expense, the airplane is 140 pounds overweight! Unfortunately, this equipment was also on an aircraft finished with over 11 gallons of Featherfil and 6 gallons of white paint (N4EZ has 5 quarts and 1.3 gallons respectively). This airplane is so heavy that a normal pilot can't even operate within the "first flight" limits shown in the Owners Manual. All of the gadgetry in this Vari-Heavy belongs in a 747, not in a little homebuilt! This airplane is now a single-place. It can happen to you, too, if you lose appreciation for weight control.

N4EZ started life with an 11-pound alternator on the engine and had to have 10 pounds of lead in the nose to balance properly. We really thought that the alternator was necessary to power our little NAV/COM on long trips. Well, we were wrong. The voltage regulator burned out on a trip to Seattle and since we were too busy to fix it right away, we charged up the little 12 Amp-hour motorcycle battery and flew another 3000 miles. Controlled airspace, radio navigation, and weather reports, we used the radio as much as ever and the battery was still strong when the trip was over. Obviously, once home, we ripped the alternator off, took the lead out of the nose, and put the voltage regulator on a polished mahogany plaque. That little voltage regulator helped us take 21 lbs. off of N4EZ's empty weight! You hard core gadgeteers should spend your efforts finding things that can be taken out to save weight, not hunting for space to add expensive and heavy grozmos!

The second major weight offender is the finishing nut. We have heard stories of builders who use Bondo on airplanes for finishing. Bondo weighs 12 pounds per gallon. Dry micro only weighs 3 pounds per gallon. We hear reports of gallons of Featherfil being used where quarts should do. ARRGH! If you wonder why we are getting gray hair, it's because you can wipe out weeks of design refinement and weight saving efforts with a stroke of your Bondo paddle!

Read and use Section V carefully and conscientiously. Don't ruin your airplane trying to make it into a sculpture! A Cessna 150 leaves the paint and finish shop only 13 pounds heavier than it went in, and it has more than twice the surface area of VariEze. N4EZ's finish weighs 18 pounds and we think that's too heavy. If you add over 20 pounds to your Eze in finishing, you have done yourself a disservice.

There has been some confusion about what to expect for the empty weight of your VariEze. The values shown in the Owners Manual are for a basic airplane without any extra equipment, no electrical system, and minimum weight finish. The average homebuilt VariEze with an 0-200 engine, with the basic electrical system (Section III) and with an average finish job will weigh approximately 600 pounds, empty. This goes the same for a VariViggen, too. While the empty weight is given as 950 pounds, the average equipped airplane will weigh about 1050 pounds.

5:00 X 5 TIRES (THE SAGA OF BIG FOOT)
In Newsletter #11 it was mentioned that the larger and heavier 500X5 tires might be creating a problem with the VariEze landing gear. Since January our suspicions have been confirmed and these "Big Feet" have been trouble with a capital TEE. The bottom line is that the 500X5 tires must not be used on the VariEze. Stick with the recommended 340X300X5; the following explains why.

The Eze landing gear is a lot like a big tuning fork. It has a distinct "natural frequency" that it will vibrate at, when excited. In the fore-aft direction, the once-per-revolution excitation of an unbalanced tire and wheel or a lopsided brake disc can cause the gear leg to vibrate at its natural frequency when the rotational speed of the wheels (Revs per second) is at the natural frequency (cycles per second) of the gear. If the natural vibration of the gear is excited at high speeds where there is a lot of kinetic energy (1/2 MV square), the vibration is violent and damaging. At low speed the vibration is mild and no cause for concern.

On N4EZ the 10-inch diameter (340X3X5) tires have to turn at about 20 mph (11.2 Rev/Sec) to excite a mild gear leg vibration. The larger (15 inch diameter) tires (500X5) have to zip along at a little over 30 mph to excite the gear. The kinetic energy is more than twice as great, and the vibration is strong enough to damage the gear attachment pads.

One builder has also found that his gear vibration was a problem with his brake mounted below the axle and was solved when he moved it 90 degrees to the correct position aft of the strut. The exact position of the Cleveland brake is not clearly shown in the plans. Refer to the drawing below. **SKETCH OMITTED**

BRAKE SERVICING AND BRAKELINE ROUTING
We've talked to a few builders who really didn't understand how to service their brakes with fluid and purge the air bubbles. First of all, aircraft brakes and automobile brakes are different, so don't expect the method you use on your car to work on the airplane. The brakes on VariViggens and VariEzes are your only low speed (0 to 30 mph) directional controls. A spongy brake requires immediate attention.

Aircraft brakes must be serviced by pumping fluid from the wheel brake up through the line into the master cylinder. This may seem basackwards, trying to make the river flow uphill and all that, but it is the correct way to do it. The magic in pumping the fluid from bottom to top is that it forces any air in the system up and out. A pump-type oil can or a squeeze bulb can be used to pump the fluid up through the system.

The routing of your brake lines through the airplane is also very important. The brake lines should run downhill from the master cylinder to the brake without any loops or high spots. **SKETCHES OMITTED**

A loop or high spot, like the sketch shows, can trap a big air bubble and give you a permanently spongy brake that even proper servicing won't help.

SHORT AND MEDIUM HEIGHT PILOTS

We have had a number of calls from medium and short pilots concerned that they might not be able to reach the controls on the VariEze and wondering what mods to make. The most common question asked is "Can I move the stick?" and the answer is no. The pilot should move forward, the stick should not move aft. The short pilot is also generally lighter than tall pilots and has a built-in weight and balance problem requiring permanent ballast in the nose. Moving the light pilot forward will help keep the center of gravity forward where it belongs. The rudder pedals as shown in the plans will adjust enough to fit pilots from 6'4" to 5'5" without changing anything. Medium height pilots may find it necessary to use a cushion to raise their eye-line for adequate visibility.

The short pilots, 5'4" down, who are building VariEze's will need to make some minor modifications to their airplanes for adequate visibility and better control reach. The obvious things to move first are the rudder pedals. The bottom pivot of the rudder pedal as shown in Chapter 17 is at F.S. 17 (approximately) and they can be shifted aft 2 1/2 inches to F.S. 19.5 without any trouble at all. The rudder pedal pivot bolts are simply located 1/2 inch forward of F-22 instead of 3 inches forward as shown on Page 17-8.

The major difference between short people and tall people is the length of their legs. Strangely enough, torso's and arms are fairly standard (compare the range of pants leg lengths with the length range of shirt sleeves on your next trip to the department store). The short troops may need to cushion themselves forward by the thickness of an extra back cushion but not much more for comfortable stick throw. Even 5'2" pilots can easily reach the stick. If you move forward, the canopy tries to force you lower in the cockpit, so as the pilot moves forward, the canopy has to move forward also. As the Owners Manual specifies, the pilot has to stay high in the canopy for good forward visibility. Short troops have two options; they can add one to 3" of foam thickness over the thigh support as a permanent spacer and use the standard seat cushion, or have an extra thick cushion made.

MAIN GEAR TESTING AND MODIFICATIONS

The drop and static load testing of the main landing gear strut has been quite extensive. The accompanying photos show the two types of tests which have been conducted; one test is a static load applied by a hydraulic ram, the other is a more traditional "free drop" test as is specified by F.A.R. part 23. Both types of test showed excellent results, even when using components that were considered rejects. The

drop test components were in most cases (We did test a good one too!) of inferior quality to the parts shipped to builders.

A few builders have asked what the weakest part of the landing gear is, and the answer is the attachment pads. Don't misunderstand, it is strong enough to do the job and then some, but it is the part we expect to break first if the system is overloaded. On N7EZ (VW prototype), it's trip through a ditch at 75 kts last summer tore the gear free of the airplane by failing the attachment layup, but the gear strut itself was not damaged and will be reinstalled on the airplane. We specifically tailored the attachment layup to fail first in a crunch because it is the easiest and cheapest part to replace.

If you choose to strengthen the attachment area, it can be essentially doubled in strength with very little additional weight using this approach. Follow Chapter 18 exactly up to the end of Step 2, then do Step 3 in two parts: First layup the 15 ply inside pad, clamp, and let cure; second, drill the 1/4 inch holes through the inside tab, then sand about 1/8 inch off the red foam tabs front and rear faces, prep sand the MG 1 and layup a 25 ply outside pad, clamp and cure.
SKETCHES OMITTED

The torsional strength of the MG 1 strut can be increased significantly by applying an external BID wrap. This adds little weight and significantly increases its resistance to splitting if a severe aft load is applied. We do recommend that you make the wrap as shown. This can be done even after the gear is mounted to the fuselage, but is better if done full length before the mounting pads are installed.
SKETCHES OMITTED **PHOTOS OF STATIC LOAD AND DROP TEST OMITTED**

VARIEZE ELECTRICAL SYSTEM
Lately we have been attacking the problem of how to provide reliable electrical power for NAV/COM and instruments without using the heavy engine-driven alternator. Note that leaving out the alternator is highly recommended for the heavy 0-200 and is mandatory for the Lycoming 0-235. It seems unreasonable to use a 60 amp alternator to provide power for an average current drain requirement of less than one amp. Why only one amp? Well, the NAV/COM generally needs to be used only five to ten minutes out of every hour. The only exception being touch-and-go's at controlled airports. Since the VariEze is not a training-type airplane, this use is not common. NAV/COM for cross-country needs to be used only in terminal areas or for a few seconds at a time to obtain a bearing or to check weather. Engine instruments (oil temperature/oil pressure) are very low current drain. The turn and bank is required only if you need to extract yourself from poor weather planning and is thus off the vast majority of the time. In summary then, we have found actual average electrical current requirements in N4EZ to be less than one amp, even including trips with all stops at controlled airports.

We are then taking two approaches to developing a satisfactory no-alternator electrical system. The first approach has already been tested on N4EZ for the last two months, including two 2000+ mile trips. It has worked very satisfactorily and its use is recommended. The second approach will be tested soon.

1. No in-flight charging. Convenient self-contained trickle charger to top-off battery when parked or hangared.

The system shown can be built from less than $10 worth of electrical components available at any Radio Shack or electronics supply store. The components can be mounted in a small box on the F-22 bulkhead. Total system weight is one pound. To use the system, simply plug in to any 110-Volt AC receptacle and turn on the switch. We generally give the battery an over-night or one-day charge every 10 to 15 hours flying, or about once a month. On a long trip, charge it over-night when hangared. Charge rate is 1/2 to 3/4 amp and will take about one day to fully charge a low battery. Do not leave it plugged in for extended periods (more than two days), or battery damage can occur. The battery is the same 14 AH Honda 750 motorcycle battery shown in Section III. Note the optional backup battery. This is a small 12-Volt motorcycle battery that can be selected (to use or to charge) if, due to poor planning, you deplete your standard battery. The smallest 12-Volt motorcycle batteries weigh only 4 to 5 pounds and will run your NAV/COM and instruments about an hour continuous.

SKETCH OMITTED

2. Solar-powered electrical. Note that we cannot recommend this as we have not yet tested it.

The solar cell panel shown costs about $170, weighs a few ounces, and should keep the battery charged if ratio of sun-exposure time to radio-use time is in excess of ten. **SKETCH OMITTED**

EXHAUST SYSTEM

One of the four mild carbon steel exhaust stacks on N4EZ developed cracks recently and had to be replaced. The cracks appear to have originated along some deep mandrel marks (left from forming) in the first bend downstream of the exhaust port. The cylinder appears, from exhaust deposits, to have been operated at a normal mixture (one cylinder of an engine doesn't necessarily get the same fuel/air mix as another even though they are hooked to the same carburetor). There are a lot of possibilities open as to the cause of these cracks. The mandrel marks alone could be the culprit. The combination of heat and vibration may require the use of stainless steel instead of carbon steel. It is also possible that the geometry of the exhaust stack is incompatible with the engine for another reason. We are evaluating these possibilities as fast as we can, however this involves flying a lot and many homebuilders will be flying before we have the final answer. This problem doesn't pose any immediate threat to flight safety but until it is resolved you should plan to inspect your exhaust system visually for cracks at least every 25 hours or engine time. In the meantime we will be testing a stainless system (same geometry) to determine if this will solve the problem.

EPOXY

Last October we began working with a large epoxy formulator to develop an alternate supplier of the RAE, RAEF, RAES and 5-minute material for VariEze construction. Meeting our specifications for this material has

not been easy, particularly for RAES. The new material supplied by Applied Plastics is now available at the VariEze distributors, and that it meets or exceeds all previous specifications. It is also less toxic to work with. Most important, we are confident that the quality control problems with the previous vendor will not reoccur. Here's what to look for if you suspect that you have problems with your epoxy. Your epoxy resin (RAE) should be clear or have a slight amber, red, or greenish tint. At 75 degrees its viscosity should be low enough so that it is easily poured. (Cold temperature makes all resins thick). The resin should not be contaminated with particles or lumps floating in it. Thick honey-like resin or contaminated resin should be returned to the place where you bought it. Hardeners may be tinted a variety of colors. A new bottle of hardener may occasionally show a milky sediment in the bottom; warming and shaking should allow this sediment to go back into solution. It should be warmed by placing the jar in hot water (130 to 170 degrees F.) Do this before using a new bottle. If the sediment will not return to solution, the pot life of epoxy mixed using the hardener will be shorter than it should be, so return it to the place of purchase for replacement. If your hardener has crud in it that doesn't drop into solution by warming and shaking, get is replaced, also. 5MIN epoxy is a very quick setting system of high viscosity. The 5MIN appears to be about twice as thick as the RAE laminating resin and takes about 5 to 10 minutes to cure out hard after mixing. 5MIN is used to locate and fixture parts and must cure out hard. Any tendency to remain soft or "bubblegum" after 1 hour is unacceptable and the material should be replaced.

EPOXY SENSITIVITY

Since last Newsletter, we have had quite a bit of mail from builders who have become sensitized to epoxy. It looks like about 10 to 20% of the builders have some mild form of sensitivity, like Burt does, and about 1 to 2% have indicated a severe reaction. Some have simply had to abandon their projects because of it; others find simple precautions adequate to avoid the allergy. We don't have a "cure-all" for the sensitivity problem but we have had some additional inputs on the subject. We have also changed to a different epoxy formulator, who is now supplying a less toxic material but we don't know if the reduction will be enough to help the severe sensitivity or not.

Epoxy sensitivities seem to be of two basic types; a systemic reaction like an allergy that can be aggravated by breathing the fumes, skin contact with the epoxy, or both; and the second is a "contact dermatitis" or rash which is aggravated by skin contact. Some people have found that an antihistamine like the 'allergy' tablets sold for pollen allergies are effective against epoxy sensitization. As well, one builder sensitive to fumes, found that an activated charcoal filter equipped painting respirator did the trick for him. Another builder is using a "space suit" H.G. Wells thought up.

Some commercial epoxy handling shops prefer to use a disposable plastic glove with a light cotton glove under it. The plastic glove keeps the epoxy off while the cotton allows the hand ventilation and snugs the plastic so that your dexterity isn't impaired. The Ply 9 skin protector is a good barrier, but it can be rubbed off accidentally by working with tools or if your hands sweat or get damp otherwise. Be aware of the limitations of Ply 9 and reapply if you think you have rubbed or washed it off. One physician on our Newsletter list advises

that your clean-up can be just as important as protection beforehand. In the process of washing up, epoxy can be smeared onto unprotected skin, so be sure you wipe away excess epoxy with a paper towel before you start washing, and wash thoroughly.

If you find yourself with an extreme sensitivity you should seek your own doctors advice. Try using all of the normal precautions but for some of you this isn't going to work. It may be that some of you simply can't work around epoxies at all and if that's the case you should probably drop your VariEze project. There is no sense in torturing yourself; building airplanes is supposed to be fun.

ROLL TRIM

It may be that some builders will find their airplanes far enough out of trim in roll that a fixed ground adjustable roll trim tab may be required in addition to the flight adjustable system shown in the plans. If your airplane requires the additional tab you should install it during your initial runway flying, before first flight. The ground adjustable tab is located on the left wing in the same position spanwise as the plans show for the flight adjustable tab on the right. The tab is .025 aluminum (2024-T3 or 6061-T6), 10 inches long and 2.3 inches wide. The tab is riveted to the wing trailing edge with six 1/8 inch pop rivets. The tab overlaps the trailing edge 1/2 inch as shown and the rivets should be located in the center of the glass to glass overlap. **SKETCHES OMITTED**

Note in the plans changes that the chord of the flight adjustable tab has been reduced to 1.7 inches. The airloads on the 2.3 inch tab were high enough to back it off of the selected position at high speeds. If you have already built the tab, trim it to 1.7 inch chord.

VARIEZE FINISHING

We have seen several examples of excess filling used in the finishing process, particularly over the wing fittings. If proper care has been used in locating the wing fittings only a feathered area around them needs contour microfill. Never stack a lot of fill over the fittings or unnecessarily high in any area (see Section V). The reason for this is not only cost and weight. Having a high separation between the white paint and the glass structure eliminates the flexing compatibility, in that the paint may crack under normal flexing without

glass damage. This flexing compatibility is important since the presence of paint cracks indicates a possible structural problem that requires paint removal and inspection. **SKETCHES OMITTED**

Note that it is better to compromise overall contour than to use excessive fill material.

WORKMANSHIP

In Newsletter #10 we encouraged builders to help "police" each other by being honest with each other and lettin' the guy doing marginal or sub-marginal (junk) work know it. It appears that most builders are doing a good job of building their airplanes but there are a few of you who aren't. We have seen a few examples of workmanship so poor that the parts are structurally unsound and cosmetically wretched. The unfortunate part of it all is that some of these builders either don't know or refuse to admit that they have created junk, not airplanes. It may be a bitter pill to swallow, but some of you will not be capable of building a VariEze. We have found a few builders who try and stretch the limits of our acceptability criteria so they can squeak by with sub-marginal workmanship. The inspection criteria published in Newsletter #10 are minimums for acceptance and they cannot be stretched for your convenience. If you know of someone who is trying to "slide by" with a junk airplane, it is in your own best interest to let him know about it in no uncertain terms. A poor safety record hurts us all. All airplanes are infernally complicated and difficult to build, some are just worse than others. The VariEze is "less worse" than most but some builders will not be capable of mastering it. If you are in this group, be honest with yourself and admit it before your pride gets you killed and puts restrictions on the rest of us. Get some help and get your workmanship up to speed before you continue.

The inspection criteria published in Newsletter #10 were not frivolous standards established to make life hard for the builder. These standards were set up to keep the structure safe and strong. An example of this can be shown in the wrinkle or bump criteria. A bump in the skin tends to trigger a premature buckling failure, and a natural tendency to peel away from the foam core. **SKETCH OMITTED**

The same type of premature skin buckling failure is the result of a dip or impression into the foam. **SKETCH OMITTED**

Keeping the skins straight without humps or dips enables the glass to carry its full load, uniformly supported against buckling by the core. Dips and humps of 1/16 inch or more are structural failures built into the airframe. The key to success is a perfect foam core. Foam core defects not corrected before glassing are the most common cause for scrap parts. Laying up glass over junk just makes it harder and more expensive junk.

VARIEZE QUESTIONS AND ANSWERS

Q. My partner and I plan to do a lot of pattern flying, touch and goes, short passenger flights, etc., in our VariEze, and we don't like the idea of having to switch fuel from mains to the header tank and back for every 15 minute hop. Is it ok if we use the original fuel system shown in Section IIA with the pump?

A. No, the fuel system shown in Newsletter #11 is a mandatory change to the VariEze. The old fuel system was occasionally prone to fuel

foaming in the engine mounted header tank and relied on the fuel boost pump to avoid a possible flame-out. Your concern about having to switch fuel tanks constantly are unfounded. The fuselage tank is rarely selected; the only time it is used is when your flight planning requires long descents with low wing strake fuel (2 gallons per side). The fuselage tank does not even need to be selected for nose down starting. Leave the fuel selector on 'wings' and the fuel in the carburetor float bowl will let the engine run for two

---

minutes at idle. The fuselage tank also provides a very accurate indication of your last 2 to 3 gallons of fuel. The accuracy of the system has allowed N4EZ to complete one flight into strong unforecast headwinds with confidence even though the fuel remaining after landing was only 0.3 gallon! In a standard production type airplane the last 0.3 gallon wouldn't even wiggle the gas gauge and an extra stop would have been made, even though unnecessary! If you're shooting touch and goes with under 1/8 fuel in the wings (3 gallon total) you should switch to the fuselage tank. If you do run your wings dry or flame-out in a steep descent with low fuel, you get a re-light in only seconds by selecting the fuselage tank. Putting the below -3 gallon descent starvation in perspective it is helpful to compare it to the average light plane. According to "Aviation Consumer," when a Cessna has an "empty" reading on its fuel gauges it can have from 2 to 9 gallons of fuel! Now, few of us continue to do touch and go's or continue a trip with gauges reading empty. The real beauty of the system is that all the wing fuel can be used in level flight and then have a reliable indication of the remaining 45 minutes of fuel (fuselage). This takes the worry out of using the last few gallons that is present with all other lightplane fuel systems.

Q. I do not speak or read in English. Do you have any plan to offer translations of the plans and instructions into other languages?
A. No, we don't. However, there is a lady in Switzerland who has offered her services. She will translate into German and French for a small fee. Contact Mrs. Dane Rowe, Langgasse 51, CH-3292 Busswil, Switzerland.

Q. If it met reliability and weight requirements, would you accept installation of Rotorways 133 Hp engine (derated to 100 Hp takeoff and 75 Hp cruise)?
A. The engine is like many others, it sounds promising. Only a professionally conducted developmental flight test program can prove the concept good or bad. If the basic engine is proven out successfully then documentation for the operator must be available also so he can operate and maintain the engine properly.

Q. I just finished my wing layup and it took my wife and I all day and half the night. I was so worn out from stippling I couldn't even eat my cookies and milk before bed. What am I doing wrong?
A. Chances are that you are doing a whole group of things inefficiently, not really wrong. First, you are probably short-handed for such a big layup. Those half dozen major layups are kind of like a quilting party, by yourself they are just work, but with a group they can be fast, satisfying and fun. Try to at least get two full time

laminators with an epoxy mixing third. You are probably spending way too much time trying to make the interior glass plies exactly the right epoxy content, stippling your life away. Try making your interior plies extra wet and fast, then spend your time on the final ply with a squeegee and a roller to get the excess epoxy into the top ply or off on the floor. When you have a monster layup to do, take a break every two hours, wash up and put new Ply 9 on, then rest for ten minutes while the ply 9 dries. Be sure you give all your tools a chance to save you work, don't tackle a major layup if you are out of paint roller covers, or without a couple of clean squeegees. Try the kit-supplied squeegee or a softer type cut from a plastic coffee can lid.

Q. The local FAA is really giving me a hard time and it sure would be helpful if they had a set of plans and newsletters. Can you send them a set?
A. No, there are several hundred offices in the U.S. that inspect homebuilts and we couldn't send them all copies; but, for FAA use only you may Xerox copies of the portion you're fighting over. You can copy the newsletters for any reason you like.

Q. I've never cut plexiglass before and I'm getting ready to trim my canopy. Any advice to offer?
A. Yes, get a copy of Cowley's "Care and Feeding of a VariEze Canopy" from Cowley Industries. Every builder ought to read it.

Q. Section IIA calls out #12 wire for the magneto switches. Isn't #18 adequate? #12 is heavy and expensive.
A. Yes, #18 is ok for the mag switches.

Q. Why do you use those tiny little slick tires? How about something with a little tread?
A. Well, tread is hard on props, it tends to pick up rocks and flip them into the prop arc. $$$

Q. To facilitate any rigging adjustments that might be required after my initial test hops I'm going to leave the side consoles off of the airplane until it's flown. Is this ok?
A. No! The pitch control stops are provided by the console and the side stick controller can be easily over-powered (pilot induced oscillations) unless the pilot has an armrest. Don't try to fly your airplane until you finish building it!

Q. Will anyone be offering a "check out" or at least a back seat ride in a VariEze for other builders to get the "sight picture" before flying their own bird?
A. As far as we know, no one plans to do this commercially. You may find other builders willing to give you a ride but I wouldn't expect to fly their airplane yourself. Keep yourself current, practice the initial test sequence in an airplane you are already proficient in, and then take your initial flight testing slow and easy.

Q. My VariEze will never have a pilot other than myself and I'm a 60,000 hour super jock who can handle anything, even blindfolded. Is it ok for me to keep my Eze simple and delete the spoiler mod in CP #11?
A. No, if we didn't feel that the spoilers were required, we wouldn't have made them a mandatory change.

Q. I mislocated my canard lift tab insert and nut plates too far inboard so I remade my lift tab as shown. Do you approve of my fix?
SKETCH OMITTED
A. No! Great Zot, reconfiguring the lift tab as you have done, puts about three times the normal load on one bolt.

Q. I like the smoother surface that I get using peel ply. Can I peel ply my whole airplane outside, saving the sanding in prep for micro and featherfil, and use less featherfil to fill the glass weave?
A. I suppose that you could do this, but it also sounds like a lot of extra work and expense. The peel ply costs $1.60 per yard and the extra epoxy to wet it out is expensive too. This approach might save the light sanding done in prep for micro and featherfill, but you would have to wet out an additional 200 sq. ft. or so of the cloth! Don't confuse finishing prep sanding with structural bonding prep sanding; they are greatly different.

HINTS FOR EZE BUILDING
-A paper cutter is excellent for cutting the zillions of little squares of glass cloth used in the wings and center spar. It even measures.

-Clamping a board on each side of the wing attach fitting while making the bearing pad layups allows you to stipple actively and keeps the glass from squeezing out over the edges. Scissors trimming in this area can be a challenge.

-Canopy. If you move the canopy forward as mentioned in Newsletter #11, be sure that you leave the cut between front cover and canopy in the same place as shown on Page 22-4. The front cover is required for the torsional rigidity of the fuselage. If the vent is too cramped to fit between the plexiglass and the edge on centerline, move it off center.

-Leading edge overlap on wings, canard, and winglets, can be done with ease and very neatly using the paint roller. As you layup the upper skin plies, use the roller to wrap the overlap up onto the bottom skin instead of stippling with a brush. The brush tends to fray the cloth as you stipple giving the cured overlap a very rough surface requiring ambitious sanding to fair. The roller leaves the cloth smooth and unfrazzled. Scissor trim each successive skin ply a bit shorter than the preceding ply giving the lap joint a semi-tapered finish requiring far less work to sand smooth, and eliminating any tendency for the plies to pull away before cure.

-Trailing edges. When making your final inspection and preparation of the foam core for skinning, look carefully for potential trouble spots. A hot-wiring defect or too abrupt curvature may tend to leave voids in the trailing edge corners between the glass and foam. If you even suspect the possibility, sand the area to a more gradual transition before laminating. A well prepped foam core makes the layup much easier.

-Throttle and mixture return springs. Section IIA calls for Century C-161 springs to be used but some builders have had trouble finding them. If you have to substitute some other spring, it should have an unstretched length of about two inches and a force gradient of about 1/2 pound per inch. Adjust for a light but positive return of the arm.

-Paint rollers. These are two rollers found in hardware stores that are excellent for laminating. A nylon, EZ Paintr, No. 9FB.99 for enamel and gloss paints on smooth surfaces. Also, Cov-A-Roll, r-33M, 5/16 inch pile mohair, by Hansteck Corp., Roanoke, Va. Also for enamel on smooth surfaces.

-Hot wire cutting. A good method to use for judging wire temperature is the cut foam surface appearance. A cratered or rutted surface indicates that the wire is too hot. A very light "hair" of plastic strands on the surface is just right.

-Builders have found that the Allen cap screws holding Rosenhan brake discs to the wheel interfere with the glass main gear leg. You can add a 1/8-inch thick aluminum spacer between the gear strut and axle to correct this or make some special flush screws like the one sketched below. **SKETCH OMITTED**

-Be sure to use Teflon tape to seal the threads of all brake line fittings.

-A soldering gun with a 1/16 inch diameter music wire tip can be handy for carving notches into blue foam. The canard red foam inserts and the rudder cable groove in the wing can be done this way.

-Peel coat should be used anywhere possible. Avoid the hard sanding of cured glass by thinking ahead and laminating a peel ply in before you quit a layup. The peel ply will help avoid the damage possible with sanding. It is ok to sand a peeled surface before glassing and it is much easier than sanding non peel plied glass. See Newsletter No 11. We have found that many builders are not using peel ply where they should. Do use it for all areas requiring a glass layup over cured glass surface, ie.

All leading and trailing edges
Outer 18 inches of wing and lower 15 inches of winglet
Front and aft faces of center section spar
All edges of all bulkheads
Fuselage sides where they join nose, cowling, bulkheads and fuel tanks
Faces of canard and wing shear web that join spar caps

-Some component weights were given in Newsletter #10. Additional ones are

Center section spar (Chapter 8) 21 lbs

Wing/winglet/rudder (Chapter 24) 41 lbs

-Carving the nose. One builder found that a black string (weighted with a nut on each end) draped spanwise over the nose helped him to visualize the contour better.

-Nat Puffer has a good solution for raising the height of his Rosenhan master cylinders. It's a simple internal thread/external thread spacer with a cross-section that looks like this sketch. (See photo - pg 14.) **SKETCH OMITTED**

-Nose gear. The cutout in F-22 which allows NG 10 and NG 11 to pass through looks like this: **SKETCH OMITTED**

If NG 11 is trimmed as shown the slot looks like the second sketch. **SKETCH OMITTED**

-Hot wiring. Some builders are finding it easier to get good straight leading edges by adding a small wire to each template at the leading edge as shown in this sketch. Instead of cutting all at once you make two cuts from the leading edge aft towards the trailing edge, one top and one bottom. You heat the cutting wire, burn into the foam and rest 1/4 inch from the template on your guide wire, heat the cutting wire for a two count, burn into the template, pause a two count and then go. The first pause gives your partner time to get into the foam because sometimes the distance is uneven. Cutting foam cools the wire therefore the pause at the template. If you were talking the wire around it would go like this: Heating up, burning in, 1/4 inch away on the wire, one-two, go, template 1-2, go, then count the normal numbers. (Renumber if you want but be sure they match on all the templates) It really helps if you say quarter, half, three-quarters when you have a long way between marks on your templates. **SKETCH OMITTED**

-Nat Puffer suggests using two carpenter's squares and two plumb lines simultaneously to set the landing gear position on the fuselage. **SKETCH OMITTED**

-Main gear toe-in check. An alternate method for checking the toe-in is shown in the sketch. With the axles installed on the gear leg temporarily (clamp), with the airplane level project the centerline onto a wall about 15 feet away. Attach a 4 inch piece of small I.D. tube to the axle mounting faces (5 min or tape) and level them. Use the tubes as a boresight to locate the projection of the axle face on the wall for each axle. Measure X, Y and Z as shown. Z1 and Z2 must be equal. Dimensions Z1 and Z2 must never be greater than the dimension Y (toe-out). **SKETCH OMITTED**

-Layups. Taking a lot longer than the plans call for? Try making your layups purposely wet, then use your squeegee to remove the excess. This method is a bit wasteful but goes much quicker.

-Elevons. A lot of builders ask about elevon dimensions and which ones are critical. Use the dimensions shown here. **SKETCH OMITTED**

-Wing and canard incidence blocks. After glassing the top side of wing or canard and before removing it from the jig (root and tip W.L. still level), Bondo a board to the top surface at mid-span which is also leveled. This board can then be used as an incidence reference which is firmly attached to the surface and isn't subject to errors in positioning each time it is used. The board remains on the surface

throughout the construction of the airplane and is removed just before finishing. **SKETCH OMITTED**

-Flox corner preparation. Try using a wood chisel with sand paper wrapped over the blade for a sanding tool. **SKETCH OMITTED**

-Winglet jig. Several builders have reported good success using the foam block left after hot wire cutting as a glassing jig for the winglet. An inch or two is trimmed off of the leftover block near the leading edge and it is 5 minute epoxied to the work bench to provide a straight custom fitting jig. **SKETCH OMITTED**

-Foam core alignment. To help realign the foam core pieces of the wing and canard for correct spar notch depth, etc., one builder drilled several holes for 3/16-inch dowel rod into the foam block before hot wiring as shown. After cutting, the sections of foam can be assembled on short dowels to aid in jigging for the spar and skin layups. **SKETCH OMITTED**

Some of the problems in foam core jigging are the result of sloppy hot wire cutting. Be sure not to rush the wire around the corners of the spar trough. Pause and move simultaneously at the bottom and top of each trough joggle.

-Foam core assembly. To avoid any gaps or heavy micro joints some builders have been spring-loading the foam cores together chordwise until the micro cures. They use a motorcycle bungee cord, twine, and some cardboard to avoid gouging the foam. **SKETCH OMITTED**

If it is apparent during trial fit that you are going to have a gap, fit a foam piece to fill it, not excess epoxy/micro.

-Spoilers. A couple of builders have reported that their spoiler torque tubes interfere with the brake master cylinders. If you run into this problem, the top of the master cylinder can be shifted aft (away from firewall) by redrilling the brake actuating arm as shown. **SKETCH OMITTED**

-Check the zero position of your elevons when using the templates to measure elevon deflection. The drawings on pages 14-3, 5-7, and 5-6 show the elevon in the neutral (zero) position. Use jig block B (pg 5-6) on the bottom to verify the zero indication of the page 5-7 template.

-Radio support. If you are installing a little one and one/half NAV/COM radio like the Alpha 200, Escort 110, or RT 553, as shown on the instrument panel drawing (A1), an undefined support bracket is required. The radio comes with a mounting tray designed to attach to the instrument panel. On N4EZ we decided to add a pair of aluminum straps from the front cover (forward of canopy) down to the radio tray for better support on the most forward (away from cockpit) end. The brackets are .025 thick and 2024-T3 sheet metal, installed as shown here. To clear the elevon tubes and push-rods, the radio must be angled down about one inch and inboard 1/2 inch from being perpendicular to the instrument panel. Be sure that the control system does not bind on the radio! The angles between radio and instrument

panel are small and not objectionable esthetically. **SKETCHES OMITTED**

-The most important inspection time on any part is immediately after you're done laying it up. This is the time in which you should get a good hand held light (trouble light or any 60 to 100 watt lamp) and walk around your wet layup looking very closely at each square inch for areas of voids, dryness, air bubbles, delaminations, excess epoxy, fiber disruption, etc. Hold that light at various angles to the surface-reflecting the light will help you see otherwise invisible flaws.

Take a brush and some epoxy with you to stipple out flaws. Don't try to inspect a wet layup by yourself, particularly if you don't have sharp vision. If you have made a layup alone, get someone else to look it over closely before you leave it to cure. Your spouse can generally find the flaws on a part that you have overlooked. Most of the unacceptable parts that we have seen were done by a builder working alone and most could have been easily brought up to standards during a thorough post-laminating inspection. Get someone to help you inspect while the layup is still wet, repair it while you can, and avoid making something you must throw away later.

-We have seen one set of wings and canard that the builder knife trimmed 1/2 inch too short. The builder ignored the trailing edge trim line (foam edge), lopping the entire glass-to-glass joint area off. The shape of the canard slot lip and the wing trailing edges were completely ruined. Be sure that you have trimmed at the trim lines shown on the templates and that your trailing edge joints are similar to those shown in the section views in the plans. Check your completed shape and chord length by setting a template on your canard and wing. Do not compromise the length and quality of the trailing edge overlap.

-Your epoxy balance must be absolutely friction-free. Use small nails in the metal tubes for both pivots.

EQUIPMENT MOUNTING NO-NOS
Every homebuilder likes to personalize his airplane and give it his own distinct cockpit appointments. This is natural and every VariEze shouldn't be a duplicate of N4EZ, however, when you try attaching things to the glass/foam/glass sandwich panel you can run into problems. You can't just put screws or rivets into the inside glass skins to mount extra equipment. Mounting to the inside skin alone will tend to peel the glass skin away from the foam core, destroying the stiffness of that panel leading to further flexing and degradation of the foam core and outside skin.

VARIEZE PLANS CHANGES AND ADDITIONS

Section I

Page	Change
6-21	2.3 inch dimension should be 1.7 inch
7-2	Section C-C shows 2-2 with two 1/2 inch

	diameter holes (not 3 pieces!). It should show only one.
Section I Page 4-8	Change 3 hour to 4 hour on skin layup time.
Section IIA Page	Change
2 of 37	4 each Century Spring #C-161 are required, not 3 as shown. 12 gauge non-shielded airframe wire (30 feet) should be 18 gauge (optional change).
4 of 37	Magneto wiring diagram #12 or #14 wire should be #16 or #18 (optional change).
14 of 37	Top view of right exhaust system. Flanges are shown with stud hole rotated clockwise 20 degrees. They should be rotated counter clockwise 20 degrees from spanwise reference. **SKETCHES OMITTED**
Newsletter #11 Page	Change
A1	Materials list for spoilers. 7 x 4 .063 aluminum should be 17 x 4.
Section VI Page	Change
Two	LB 10 The "ear" which joins LB 10 to the helper/snubber springs must be 1/2 inch longer to avoid interference with LB 3 during operation. **SKETCH OMITTED**
Owners Manual Page 36	Add the following statement "Before conducting the tests on this page with your new VariEze, do all of them first with two different airplanes in which you are proficient, ie. a Cub and a Cherokee. These maneuvers (nose wheel liftoffs and runway flying at low power) are a little strange to the average pilot. Doing them in a familiar airplane takes the strangeness out of the maneuver and better prepares you to do them in a new airplane. It also gives you a first hand look at runway length requirements and weather conditions. These maneuvers are important to determine the trim of your aircraft before first flight. Do not ignore them."

Owners Manual Page 5	Delete references to 500-5 and 4:10-3.50-5 tires and add the statement "larger tires are prohibited."
Owners Manual page 30	Under 'Main Gear', add tire inflation pressure 55 PSI. Low tire pressure can lead to tube pinching or tire failure.
Owners Manual Page 28	Revise the allowable weight and Cg diagram as shown below. Note that this provides a 1/2 inch restriction in the forward cg and moves the first flight box back 1/2 inch. This change is not done for the normal reasons to restrict forward cg (flare capability in-ground-effect or takeoff rotation speed). The restriction is due instead to the tendency for the down-going elevon to stall at large aileron inputs, (see Newsletter #11 under "Spoilers") a characteristic which increases at forward cg. **GRAPH OMITTED**
Section III materials list	Switch type V3JV7 should be V3-1001JV7

FLIGHT TEST DATA
This chart is a plot of engine (propeller) speed in level flight at various airspeeds. The data is from N4EZ without wheel pants at a density altitude of 9000 ft. **GRAPH OMITTED**

VARIEZE PERFORMANCE
The following data are the average performance obtained on the last several long trips with N4EZ. It is generally cruised at 60 to 65% power near 10,000 feet and still does not have wheel pants.

cruise speed block-to-block = 179 mph (156 kt)
cruise fuel flow = 5.5 gal/hr (33 lb/hr)
miles per gallon = 32.5 sm (28.4 km)

VARIEZE ALTERNATE ENGINES
Development work is still continuing on the Lycoming 0-235, Honda Civic, and VW engines for possible acceptance for VariEze use. Insufficient data are available to make any conclusions at this time. It is likely that we will have some concrete information by newsletter 13.

VARIVIGGEN ACCIDENT On 21 February 1977 Jim Cavis was seriously injured and the forward portion of his VariViggen destroyed when it crashed during taxi tests. The exact cause of the accident is not completely understood, however a description of it and our impression of what might be done to prevent reoccurrence is presented in the following:

First, a description of Jim's VariViggen - it has a 180-hp Lycoming engine with a fixed-pitch 69x69 wood prop, composite rudders, and standard-outboard-wing-panel shape, built from composite construction (structurally similar to the SP wing). It used a two-piece canopy (windshield and canopy "A" being one piece) and did not have the rollover structure (chapter 11).

Burt Rutan was on his way home from the Denver workshop in the VariEze, stopped by to assist Jim in his preparation for tests, and was present at the time of the accident. Inspection of the airplane prior to taxi testing revealed the following: the left vertical fin had a washout of about two degrees at the tip, such that right rudder would be required to trim the airplane directionally. The main wheels were located at F.S.=132.8, rather than at approximately 130. The initial weight and balance indicated a tail heavy condition, which was corrected by bolting 33 pounds of lead to the F20 bulkhead, bringing the cg for a 185-lb pilot into the aft portion of the allowable cg range for first flight (20 gal fuel). A custom electric actuator was used to actuate reflex control. Reflex travel was not accurately measured, however it appeared that the reflex authority was greater than the specified two-inch motion. Control rigging appeared to be satisfactory.

The aircraft was assembled at the Falcon airport at Scottsdale, Arizona for taxi tests the morning of the 21st. Initial low speed taxi tests were conducted without problems except for poor brake effectiveness which was corrected. Several hours were spent doing low and medium speed taxi runs, checking systems, etc. During one of the initial low speed taxi runs it was noted that there was an apparent binding or jamming of the aileron control. This apparent hangup disappeared. A complete inspection of the control system revealed nothing and the binding did not reoccur. Ground cooling on the 180-hp engine was satisfactory.

Since Burt had considerable VariViggen time, it was decided that he do the initial high-speed taxi tests. He conducted the following highspeed runs on the 4300-ft runway 22:

1. The airplane was accelerated to 45 mph, power was then reduced to idle and during rollout the stick was pulled full aft which rotated the nose wheel slightly off the ground. The nose came back down as the airplane decelerated. Right rudder and brake were required during the acceleration to maintain heading. Reflex was full up.

2. The airplane was accelerated to about 50 to 55 mph, power was then reduced to idle and the stick was brought back to rotate the nose. The nose rotated and was maintained about one to two feet off the ground using a stick position of about half-way from neutral to full aft. At about 40 mph the nose came down. Again it was noted that some right rudder was being used and pitch control felt correct. Reflex was full up.

3. The airplane was accelerated to 65 mph and power was reduced to about 1/4-throttle. When it was noted that speed was constant, the stick was brought aft to rotate the nose high enough so the airplane was light on the mains. The airplane felt in good trim so the nose was rotated further and the airplane lifted off in level flight. The airplane was flown about 600-800 feet down the runway at a height of

one to three feet. Power was smoothly reduced to idle and an uneventful landing and rollout made. Aileron control seemed in trim during the flight (stick centered). Some right rudder was required, and it was noted that after reducing power to idle the stick was nearly full forward to trim the airplane at 65 mph. Trim change due to power at low speeds is normally high (see "VariViggen Owners Manual") however the up reflex authority of this airplane seemed a bit too much, so the reflex was run down about one to two degrees for the next run.

4. Object of this run was to determine a nosewheel rotation speed for full power and to make another runway flight. Full power was applied and maintained until the aircraft was airborne, then smoothly reduced to idle during the flight. The nose rotated at 65 mph, the airplane flew about 1000 ft at about 5-ft altitude and made a smooth, normal landing and rollout. The airplane seemed well in trim except for the requirement for a bit of right rudder. Reflex position appeared to be satisfactory and adequate for the first real flight. During the short runway flight the wings were rocked to check aileron response. Nosewheel rotation speed was normal for full power.

5. Run four was repeated with identical results.

Burt taxied the airplane back to midfield and commented that the airplane flew well and that he felt it would be ready for its first real flight the next day, after installing a small trim tab on the vertical fin to correct the left yaw trim. Jim got in the airplane to taxi it back to the hangar, but then decided instead to do a couple more medium-speed taxi runs and mentioned that he might try a nose wheel lift off. Burt told him that at idle the nose could be raised at 45 to 50 mph and cautioned him to stay below 50. Jim felt that his current flight proficiency was low.

Jim made a taxi run at about 40 mph, then another in which he reduced power at about 50 mph and raised the nose wheel. The nose wheel was about one to two feet off the ground for a ground roll of about 400-500 feet. Taxiing back, he did not stop at the observers to discuss his run. We assumed that his intentions were only to repeat his nose wheel lift off. On the next run he maintained power on acceleration until a higher speed was reached, approximately 60 mph. He reduced power, but only to about 1/3-throttle. He rotated the nose and rolled about 400 feet with the nose wheel off the ground. He then reduced power, the nose came up a bit and the airplane became airborne. The airplane then flew about 600 feet, wings level, and climbed to about 10-feet height. Power was observed to increase, then abruptly go to idle. The nose then pitched up some more and the airplane rolled to the right, striking the right wing tip on the ground immediately off the runway. Next ground contact was the right canard, then the airplane's nose and canopy as it rolled further right to a nearly inverted position. It slid 60 feet to rest, in a heading 45 degrees to the right of runway heading.

Jim received a very serious head injury and a broken wrist. At this writing his condition was improving but not yet to the extent that he could recall any details about the accident. It is not known whether he had intended to make a lift off or to merely raise the nose.

The entire forward fuselage forward of F.S.90 and the right canard was broken up. The fiberglass pieces (nose cone and visor) are intact, but the majority of the wood fuselage structure was destroyed. The fuselage fuel tank was crushed about 10" and leaked in one corner; there was no fire. The engine, engine mount, and all components in the engine area remained

---

intact, inplace, and undamaged. Both vertical fins were undamaged with the exception of the top front corner of the right fin. The entire inboard wing, main landing gear, and left outboard wing were undamaged. The composite right wing's foam core was shattered from the tip inboard about 2-1/2 feet. The glass skins were intact. The right outboard wing, including attachment was undamaged inboard of a location three feet from the wing tip.

A description of what happened is easy. An analysis of why it happened is not. The airplane's motions in pitch are explainable and understood. The reason the airplane rolled to the right is not known; we can only speculate. We do not believe Jim was intending to lift off, and thus was surprised and shocked to find himself airborne. After the short flight had progressed in an accelerating and climbing fashion he probably realized that the end of the runway was quickly approaching and thus slammed the throttle to idle. At that point he still had 2400 feet of runway left, but at ten feet altitude and climbing, we're sure the runway looked quite short to him. It did not appear that he countered the airplane's natural nose-up trim change when power was reduced, but that is only speculation.

Why did the airplane roll? Could it be the airplane stalled and thus dropped a wing? Possibly, but this is not likely since the angle of attack did not look excessive and N27VV, the VariViggen prototype, shows no tendency to drop a wing during stalls, even at idle power. Could the controls have failed or jammed? Inspection of the wreckage showed all controls intact. The nicopress sleeves on the roll cables passed within 3/8" of a rib and the cable ends were frayed such that this may have hung up the controls. This, however, seems unlikely; a similar rigging exists on N27VV and no jamming has been noted in over 600 hours of flying. Possibly Jim was disoriented due to the shock of the unexpected flight and nose-up trim change such that he was unable to control the airplane. Possibly he was partially blinded by the sun which was just above the horizon directly in front of him. The airplane's out-of-trim condition would have had a tendency to make it turn left, not right, so that seems to have no bearing on the cause of the right roll.

Now, what can you, as a VariViggen builder do to prevent reoccurrence of this tragedy when you conduct initial tests of your airplane? The following procedures should be followed. You will note that they are essentially the same information that is in your owners manual, with added emphasis.

Airplane Preparation

Be sure your weight and balance is conducted accurately. Your calculated cg with the pilot should be checked by weighing the airplane with the pilot on board. Cg should definitely be within the first-flight box, preferably at F.S.122. Check control surface travel: elevator 29 degrees down, 10 degrees up minimum; rudder 29 degrees outboard, 11 degrees inboard +-3 degrees. Set reflex position to obtain the neutral position of the ailerons as shown. This is approximately mid-reflex. Use this reflex position for your initial tests. True, a lower rotation speed can be obtained with up reflex, but using mid-reflex will assure that you have ample elevator control authority even if you have errors in construction, such as incorrect canard incidence, warped wing, etc. **SKETCH OMITTED**

Maximum aileron travel about this neutral position is not as important, should be approximately +-10 to +-12 degrees.

Pilot Preparation

There is no such thing as a minimum number of hours a pilot should have to be qualified for initial test flying. The best pilot qualification is variety. He should be current in more than one type of airplane. The VariViggen is not difficult to fly, but it is different; like a Yankee is different from a Cessna, or a Cub is different from a Cherokee. A pilot who is used to the differences between a Cessna and a Cub, is ready to adapt to the differences in a VariViggen. So, get some current time in a variety of airplanes. Also, shortly before you do your high speed taxi tests and lift offs, do those tests with another airplane. Doing a nosewheel rotation with idle power, doing a short hop down the runway at one to three-feet altitude, etc., is something a little strange to the average pilot. Doing a few of these in a Cherokee or Yankee takes the strangeness out of these maneuvers in a familiar airplane and better prepares you to do them in a new airplane. It also gives you a first-hand look at runway length requirements, weather conditions, etc. Do wear a helmet and shoulder harness for your initial tests. Jim's injuries would have been far less severe had he been wearing a helmet.

Test Procedure

Follow carefully the ground tests and high speed taxi procedure in the VariViggen owners manual. Be sure to reduce power to a low setting or to idle to avoid accelerating to a higher speed when you do the nose wheel lift-offs. Use the mid-reflex position shown above.

Follow the lift-off procedure shown in the owners manual, using mid-reflex. Before lift-off be sure to reduce power sufficiently to avoid accelerating, and above all, make power adjustments slowly and smoothly. The only unusual thing about the way a VariViggen flies is the trim change due to a power change at low speed. This is quite easy to get used to, if power adjustments are made slowly. After you have several hours in the airplane you will find that countering the trim change is not difficult even for rapid power changes.

Follow the first flight procedure in the owners manual using mid-reflex. The prototype, N27VV has satisfactory pitch control authority throughout the entire eight-degree reflex range. However, due to tolerances/inaccuracies in construction you may find that your airplane

is different; for example, at aft cg, up reflex, and idle power, your stick-forward (down) control may be limited and thus you should limit up reflex travel, or conversely, at forward cg, down reflex, and full power, your stick-aft (up) control may be limited at low speed. Thus, you should rig your airplane to limit down reflex travel. So, follow the envelope expansion section of your owners manual carefully. Make cg changes and reflex changes a little at a time and evaluate all conditions of speed and power (at altitude) before further changes. Thus, if your airplane is rigged or built differently than N27VV, you can safely determine a comfortable cg range and reflex authority for your airplane. Once this is determined be sure to placard your aircraft, limiting pilot weights to remain within the allowable cg range. Set the reflex stops to limit its authority to the range which you are comfortable with.

We are making the prototype N27VV available to VariViggen builders who have completed their airplanes so that they can get a frontseat checkout. Those of you who have a VariViggen nearly completed and have good current pilot proficiency are encouraged to get some dual in N27VV before conducting your flight tests.

VARIVIGGEN PLANS CHANGES AND ADDITIONS

Owners Manual	Add the information from "VariViggen Accident" to your Owners Manual.
SP Wing Plans Clarification	The drawings do not show the inboard glass rib which is discussed in the text. The sketch below gives the general arrangement. **SKETCH OMITTED** The trailing edge of the SP wing has a kink in it at the outboard end of the aileron. This is normal and due to the change in taper and sweep which occurs at this butt line.

SHOPPING

WANTED
Steven Sterner, 317 S. Washington Ave., Sabetha, Kansas 66534 is interested in buying a partially complete VariViggen project.

Buyers Beware
The Anderson Engineering Co., Florrissant, Mo. has been dragging out deliveries of hot wire controls excessively. Better look elsewhere.

FOR SALE
1 run out C-85 Continental, $350. Call Dave Bassett 503-378-8227 (work) or 503-476-2021 (evenings).

Epoxy ratio pumps. Gougeon Bros. has announced an improved version of their "mini" pumps which is made of a more expensive, but inert, plastic. The new "super mini" pumps sell for $9 a set.

Fuel strakes. Jiran is now offering prefab composite wing strake fuel tanks. These are very nice looking parts and they add about 4 gallons to the total fuel capacity.

DISTRIBUTORS REPORT

JIRAN:	F.J.G.R. reports that they are meeting the main gear shipping schedule published in their most recent letter. The engine cowlings are now off-the-shelf item with no shipping delay. Canopy frames and mounted canopies are also very close to being backlog free. Jiran is now producing wingstrake/fuel tanks and these are very handsome parts. The molded, vacuum laminated parts are a tad lighter and hold about 4 gallons more fuel than the plans Chapter 22 tanks.
BROCK:	Ken reports that wing fittings, one of the big delay items, are now caught up to orders placed through February '77. All of the other parts appear to be moving along steadily. Ken and his troops are now producing the bulk of the landing brake parts and spoiler system parts, but they haven't gotten into his catalog yet. Ken reports that he will have a catalog addition out soon and it will include price and availability of the raw unmachined aluminum castings.
AIRCRAFT: SPRUCE & WICKS ORGAN	It looks like the backlog of orders, and the wait for materials, has finally calmed down. New kit orders are now being shipped within 3 to 4 weeks. Some minor items, like wheels and brakes, still seem to be coming in later than the bulk of materials, but the backlog on these items is disappearing fast now that the manufacturers are on line.
COWLEY ENTERPRISES:	Canopies are basically off the shelf, immediate shipment items.

Cowley's have opened a facility on the Mojave airport. The address at Mojave is Building 170, Mojave Airport, Mojave, CA 93501.
Note that there is now a source for Vari Viggen canopies - check the distributors list included with this newsletter.

THANK YOU FOR YOUR INTEREST IN THE VARIEZE TWO-PLACE SPORTPLANE

**PHOTOS OMITTED

THE STORY
For the last 12 months, we have refrained from promotional activities and marketing on the VariEze to concentrate totally on its development and setting up materials and components distribution. In this short time, we have 1. flown a full 350 flight-hour test program on two prototypes, one Continental and one VW-powered, 2. completed full structural qualification testing, 3. prepared a manual for the amateur builder to educate him in the structural materials and to guide him through construction, 4. set up a materials distribution system through established, competent distributors.

THE TEST PROGRAM
The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE RESULTS
The VariEze has superb flying qualities for its primary mission - comfortable travel. It has excellent hands-off stability even in turbulence. It is unusually safe at low speeds, can be flown with full aft stick (47 kt) without being susceptible to departure or spin, regardless of attitude or power. Performance is also superb - cruise up to 200 mph and climb up to 1700 fpm at gross weight with the larger engines.

THE MISSION: PRACTICAL UTILITY
Although quite compact outside, the VariEze provides unusual comfort for up to 6-ft, 7-in, 210-lb pilots and 6-ft, 5-in, 220-lb passengers, plus two medium-size suitcases and four small baggage areas. The 24-gallon fuel load allows up to 1000-mile range at economy cruise. High altitude climb is excellent, for flying over turbulence, mountain ranges, and for satisfactory high-density altitude take offs.

THE DESIGN
The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic systems design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE STRUCTURE
New composite sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, longer life, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair.

THE HOMEBUILDER SUPPORT
The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter,

"The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations. Construction seminars are provided at RAF and elsewhere.

THE AVAILABLE HOMEBUILT
Established, competent distributors have stocked materials and components before the aircraft was marketed. All raw materials are now available plus many prefabricated items including canopy, landing gear, wing quick-disconnect fittings, cowling, all machined items, rudder pedals, engine mounts, suitcases and upholstery. If you choose to purchase all prefab parts, you can build your VariEze in about 500 man-hours - really!

VariEze documentation is available in five sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full-size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words! The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, A75, C85, C90, 0-200
SECTION IIB - VW engines (avail. Oct '76)

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system, avionics, landing and position lights, antennas, starter. Avail Sept. 76

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim. Avail Sept 76

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

The following are RAF-authorized distributors of materials and components. Items indicated have been developed under RAF approval and are recommended for VariViggen or VariEze aircraft. Contact the distributors at the address shown for his catalog and description of items. Indicate to him that you are a VariViggen or VariEze builder.

FLASH - AILERONS CORRECT VARIEZE ROLL DEFICIENCY
April 16, 77

BACKGROUND - One of the first homebuilt VariEzes to fly was Tony Ebel's. Tony has flown it only once. Tony took off from a runway too short to allow a trim-determining runway flight instead of following the flight manual-recommended procedure. As he climbed and accelerated he found his airplane had a severe left yaw tendency requiring nearly full right rudder to control. He flew the pattern with cross-controls to keep things upright, made his approach and a safe landing. Tony is an experienced Pitts pilot. A less experienced person might not have been as lucky. His airplane has an incorrect washout in one wing and large unsymmetrical discrepancies in the winglet airfoils. While the reason his airplane flew so crooked could have been predicted by measuring his airframe, we were concerned that even though we have repeatedly emphasized the importance of building a straight airframe, some of you may find your first flight as harrowing as Tony did. Knowing that rear wing ailerons have the potential of much higher roll control capability and that they would definitely solve the partial stalling of the down-going elevon, we felt that even a crooked airplane could be safely flown. We decided to develop rear wing ailerons for N4EZ and use the canard controls only for pitch (elevons become elevators).

REAR WING AILERON SYSTEM
Design and construction of the aileron system including manufacturing of all parts and installation in N4EZ required approximately 80 man-hours over a five-day period. Cost of materials was about $45 more than the elevon system. The new system consists of a single pushrod from a modified stick to the canard elevators. The stick mounts on a torque tube extending to the rear seat stick and extends to the firewall (yes, dual controls are not only simple now, but quite practical). Pushrods extend to belcranks near the wing attach fittings and pushrods extend aft to the aileron arms. All controls are within the confines of the cowling; nothing is external. The ailerons extend from the inboard wing rib out to B.L.74. The wing is easily modified, an inside glass layup providing a new aft spar. The spoilers are eliminated.

FLYING QUALITIES IMPROVED & DUAL CONTROLS ADDED
While the roll qualities were improved with the spoilers, the airplane still had a sluggish feel in roll and still had some coupling (pitch inputs when roll was commanded) particularly at forward cg. We have of course been concerned that this deficiency would reflect on the canard

configuration itself, a reputation it does not deserve. The aileron-equipped VariEze now has excellent flying qualities and safety in all respects. Its roll rate is comparable to a Yankee. Its roll rate qualities are superb, with minimal adverse yaw. Its crosswind capability is greatly improved. Its "hands off" stability is retained, and its roll/pitch coupling is gone.

Now for the big question: should you install them on your airplane? We strongly encourage all of you to install the ailerons. Consider them mandatory if you suspect that your aircraft is not built straight, or if your pilot proficiency is not good since they increase roll control and the airplane flies more "conventional." The new flying qualities not only make the airplane safer for crosswinds, but they allow incorporation of a rear-seat stick and throttle for those wanting fly-home-and-land capability in the event of pilot incapacitation.

Flutter and stall tests are now being conducted. Plans for the modified control system are being drawn and will be available by about 7 May 1977. The plans are free, but you are being asked to provide the postage. Plans can be picked up at RAF after 7 May or will be mailed to you if you send us a self-addressed 9" x 12" envelope with 57 cents postage ($1.50 for air mail over seas). PLEASE include your aircraft serial number. Those of you who have just installed spoilers are probably upset & asking "what's next"? We can assure you there will be no further redesign of the control system. We are completely satisfied with it now. Changes cause us considerable hardship too!

THE CANARD PUSHER NO. 13 JULY 77

NEWSLETTER SUBSCRIPTION - $4.75 per year
OVERSEAS (AIRMAIL) - $6.50 per year
BACK ISSUES - $1.00 each

If you are building a VariViggen you must have #1 thru current.
If you are building a VariEze you must have #10 thru current.
The "Canard Pusher" is published quarterly: Jan., Apr., July, and Oct. by

Rutan Aircraft Factory
Bldg. #13, Mojave Airport
Mojave, Ca. 93501
(805) 824-2645

RAF ACTIVITY since the April newsletter has included a complete flight-test program on our new aileron-equipped VariEze, support of builders and flyers of the VariEze and VariViggen, two Mojave flight demo days, VariEze trips to the Chino and Watsonville Flyins, check-outs for some VariViggen builders, further structural research, VariEze flying for a movie project, VariEze evaluations by several aviation writers, and development of a homebuilt homesolar water heater.

Except for the VariEze's exhaust system, both the VariEze and VariViggen have been maintenance free since newsletter 12.

You are invited to visit RAF to inspect our airplanes. If you are building, bring parts from your project so we can help with inspection, etc. Our regular hours are 9 to 5 (with a lunch break), Wednesday through Saturday. Builders who need construction assistance may be able to catch us by phone at other times, but we may be in the shop with epoxy up to our armpits, so try to call Wednesday through Saturday if you can.

HOMEBUILDER FLIGHT REPORTS At last count there were eleven VariEze's and one VariViggen flying (not counting the airplanes at RAF). We understand that Bob Conn flew his VariViggen first flight on May 20, but have little information from him. Bob, how about a report for the next newsletter? You VariEze flyers are also a bit tight on info when you are busy on your flight test programs. The following has been gleaned from letters and calls from those now flying. How about a good report from you guys for the next newsletter. As far as we know all VariEze's that have flown are now in current flying status. Maybe some will have restrictions flown off and will make it to Oshkosh.

Peter Krauss, Stuttgart, Germany - Peter has already flown to at least four airshows in three European countries, including the big Paris airshow. Peter reports his first flight was a bit tricky because even though he felt his airframe was straight, it was out-of-trim enough to require rudder to keep things upright (this was with elevons, of course). Second flight on were okay after installing another roll trim

tab on the wing. Peter has experienced the same exhaust system cracks as on N4EZ (see later in newsletter) and has modified the exhaust system. He has found, as we have, that the Cleveland brakes are more effective than the Rosenhans and result in less runway required for landing. Peter has done a lot of flying in rain with his VariEze and has noted an unusual phenomenon. Due to the difference in airfoils and loadings of the wing and canard the airplane trims nose up when wet in a rain shower. When rain is encountered you have to hold forward stick pressure and this disappears after the airplane dries out in clear air! Now that the Paris airshow is over Peter has brought his airplane back into the shop to install the ailerons. Incidentally, Peter has produced an 8mm sound movie (in German) covering the construction aspects of his VariEze.

Tony Ebel, Lompoc, California, who we reported on in CP 12 as also having a tricky out-of-trim first flight, is now flying again, this time with ailerons. He reports that he really likes the ailerons and finds the pitch control a bit sensitive. He still has a crooked airframe, particularly the winglets, which results in an out-of-trim condition at high speed, but it is easily controlled now with ailerons.

Lee Herron, New Jersey - "VariEze N1WX flew on Sunday, June 18 for one hour and all went very well. We have a heavy right wing--a trim tab on the left wing has corrected it and she now flies hands-off for thirty-minute periods. All in all--thanks for a great aircraft design. She is fast--outruns everything around here and does everything I ask of her. All the Bonanza owners hate her. We now have 17 hours and will see you in Oshkosh shortly." Lee's airplane has ailerons and a Continental C-90 engine. Lee has noted a 1/8 quart oil loss per hour through the breather. I lose about 1/10 quart per hour on N4EZ. I'm going to try to relocate the breather hose to the top of the starter cover plate, since I suspect that the oil loss occurs only during a steep climb. Lee had earlier damaged his airplane when he made a high-speed taxi test without locking the canopy. The canopy blew open and he had a locked brake due to the use of automotive brake fluid. This swells o-rings and ruins brakes. Use only aircraft brake fluid.

Cy Mehling, Pennsylvania - "Be it known that on the evening of 16 June '77 VariEze S/N 3 lifted off the runway at Doylestown, Pa., flew over the surrounding terrain for about one hour and disrupted every household, picnic, graduation exercises, and all other associated activities in this little town as first eyes turned upward, followed by a mass migration to the airport. This morning it's hard to comprehend that just nine months and twenty days ago those big boxes of foam arrived from Aircraft Spruce. Mary and I send our greetings and heartfelt thanks for the many times you have helped us in the past and an astonishing design for our new airplane." Cy's airplane has an O-200 and ailerons.

Wicks Organ Co., Illinois - N101MW is again flying after its layup to install ailerons. George Gibbons made three flights the first day out and reports he likes the flying qualities, except he felt it was a bit sensitive in pitch until he got used to it. George reported that it was a real strange sensation on his initial taxi tests because of the pilots position out in front of the slim cockpit, but this feeling disappeared after being airborne. George also mentioned that although he made good landings, it was difficult to teach himself to "drive it

on" per the Owners Manual instructions, since he had been taught to always make full-stall landings.

Gordon Olsen, Oregon, flew first flights in April. His highly modified VariEze, powered by a Continental C-85 has reflex adjustable ailerons, a modified tapered canard and a novel instrument panel that lifts with the canopy. Gordon is a competent engineer, using his VariEze for some interesting aerodynamic research.

Kibler/Cowley/Kern, California - The Honda-powered VariEze has been out of flight status lately for some engine updates and installation of ailerons.

As I am writing this I received a call from Johnny Murphy, Florida. His C-90 powered VariEze made its first flight today. Johnny was pleased with handling, had good cooling, and made an uneventful landing. He commented that, like George Gibbons, he had made a full-stall landing even though he was aware of the recommendation to drive it on at 60 kt. During this first flight he experienced an engine failure. He switched the fuel valve to the fuselage tank and the engine immediately restarted. He had not yet checked his fuel system to determine the problem, but he suspects that his Bendix-type carb may require a larger fuel lead. He will, of course, recheck his fuel system and he intends to install the Marvel Schevler carb.

To all those flying, our hearty "congratulations." There are few experiences as exciting as first flights in an airplane you have built with your own hands. Add to that the intrigue aroused by watching your unusual shadow cast on the ground, and the ease at which you can out climb your chase plane and this adds up to one very fulfilling experience!

A comment is in order for those who are, or will, experience pitch sensitivity. Over controlling the airplane in pitch is generally due to the pilot forcefully ham-handing the controls because he is apprehensive and is concerned about "getting behind it" on first flight. A side-stick control is set up for lower control forces than a wheel or center stick, because the arm is rested on the armrest and only the wrist action is used to control. Heavy forces are tiring for a wrist control, thus light forces are designed in. However, if you are flying with your arm off the armrest and using your arm muscles to control the stick, the forces will feel too light. The airplane has excellent damping and stability with hands-off controls. So, rest your forearm on the armrest, use smooth wrist action for control and above all, relax. The VariEze flies smoothly by itself. Smoothly steer it where you want it to go, don't force or jam it back and forth. Of course, pitch forces increase at forward cg. If you are uncomfortable with the forces, move the cg forward until your transition is completed. Also, be sure to use cushions as required to place your head up nearly touching the canopy for the best forward visibility.

OSHKOSH 77 The RAF office will be closed from 25 July to 12 August for our annual Oshkosh, Wisconsin trip for the EAA convention. There will be forums on the VariEze at Oshkosh on 31 July and 5 August. A

VariViggen forum will be held on 2 August. Burt Rutan will also give a lecture on flight testing on 4 August. VariEze construction workshops are scheduled for 1 August, 3 August, and 6 August. We will also have our booth open all week--this will be a good place to get your building questions answered since the booth will be manned by active builders. Do bring parts of your project so we can help you with any inspections and better answer your building questions. We should also have a sound movie produced by Ferde Grofe Films. The film shows VariEze, N4EZ, in action, including preflight, taxi, takeoff, mountain flying in some narrow canyons, low-level strafes, landing, etc. Film was shot from the ground, chase car, chase aircraft, and from the VariEze's back seat. Ferde Grofe Films will be marketing the film in Super 8, 16mm, and video cassette for sale and rental. Contact them for price and availability. --18139 West Coastline Drive, Malibu, Ca. 90265.

VARIEZE AILERONS As you know, the VariEze underwent a major control-system design change shortly before newsletter 12. At that time we had made only a few flights with ailerons but were already convinced that they were a very important addition to the airplane. Aileron plans were first available on the first of May and we hope that all serious builders have received them and updated their plans and airplanes to this configuration. If you have plans and do not have the aileron addendum send RAF a 9"x12" envelope with 57 cents postage ($1.50 overseas) and with your address written on the front. Include your aircraft serial number. RAF will stuff your 9 x 12 envelope with the 19-page aileron addendum, thus updating your plans. There is no charge for these.

RAF has gone to considerable expense in developing the aileron system, including (1) a full flight test program revalidating the airplanes performance, flying qualities at all cg's, absence of flutter above the dive speed, absence of spin susceptibility and crosswind capability, (2) preparation of drawings and assuring the availability of parts thru distributors, (3) absorbing some of the loss due to obsoleted items (spoiler parts and VECS 5/6).

Of course, the big question is why, why we waited until this late to remove the roll function from the canard and add ailerons for roll?

The reason we did not originally use conventional ailerons is that we were obsessed with the simplicity and low cost of the elevon control system. We knew that it did not provide optimum flying qualities in that the roll rate was sluggish unless rudder were used, and that large aileron deflections resulted in the elevon being deflected far enough to cause a partial stall on the down-going surface. This produced a mildly objectionable pitchdown when large aileron inputs were used at low speeds, particularly at forward cg. Installation of the small spoilers on the cowl offset this somewhat, but did not cure the cause. We had assumed that these objections were minor enough to accept and that keeping the simple control system was justified. The fact that the airplane required rudder to maneuver well at low speeds was documented in the Owners Manual, including the requirement for good rudder proficiency for the pilot before being qualified to fly the airplane.

We did not consider the sluggish roll rate to be a flight safety consideration, merely a minor objection that the pilot easily gets used

to as he builds his proficiency. Well, to be blunt, the initial homebuilder's experience showed that we were wrong. We found that far too often people just don't do what you tell them to. They don't determine roll trim in a ground-effect flight as the Owners Manual instructs. They fly without roll trim or with a crooked airplane or without the appropriate pilot proficiency. Worse yet, we have found that even small differences in the wing airfoils, winglet angles, or wing twist caused enough out-of-trim that three out of the first six homebuilt VariEzes to fly with elevons found that they had to use rudder just to keep things upright. This being the case, we are forced to make installation of the rear wing ailerons mandatory for everyone.

Now, for the good news. The aileron-equipped VariEze adds some important capabilities to the airplane in addition to its stronger roll authority required to offset an out-of-trim airplane. Returning the strongest roll control to the stick, rather than the rudder pedals made it quite practical to add a rear stick to allow a rear seat passenger to fly home and land in the event of pilot incapacitation. The rear seat stick is included in the aileron plans. The canard control surfaces are now used only for pitch control and thus their effectiveness is not compromised to allow large deflections for roll. As a result, they are much more effective in their role of giving the canard its high lift required at forward cg. Whereas the VariEze used to be limited to pilot weights below 210 lb., the forward limit cg is now extended and pilots weighing up to 255 lb. can be accommodated. The forward cg limit is now based on structural considerations on the nose gear strut; even at forward limit cg of sta 95 the VariEze has more than enough elevator power to rotate the nose before lift-off speed and to flare in-ground-effect.

The aileron-equipped VariEze can now do good conventional sideslips, a maneuver that was very limited with elevons. Sideslips aid forward visibility during steep climbs and greatly increases the airplanes capability to make a good landing in a gusty crosswind.

Most important, the airplane now flies more "conventional", in that roll authority is stronger on the stick rather than the rudder pedals. This should greatly shorten the time required for a pilot to transition to the point where he feels comfortable. We were also concerned that the sluggish roll rate would reflect on the canard configuration in general. A reputation it does not deserve.

Another thing we found through the homebuilders experience was that the spoiler system was unacceptably susceptible to errors in workmanship in installation and rigging. Within the first ten airplanes we inspected we found three who had the spoilers rigged improperly or were rubbing on the cowl! Thus, we were quite pleased to put the entire spoiler system in the trash can where it will never get out of rig or jam on the cowl.

One of the early reasons we were reluctant to incorporate ailerons was our fear of a rear wing flutter mode that may be divergent. This is why we designed the ailerons in the configuration of a full-span mass balance. Flight tests have shown the airplane to be free from flutter. The highest flutter test point was at 240 mph indicated at 10,000 feet, which is a true speed of 280 mph. All controls had deadbeat damping at this speed, thus demonstrating adequate margin over red line speed.

We had previously preached that the "clean wing" of the VariEze (no control surfaces) provided a performance advantage. We were wrong. We have been unable to detect any speed loss due to the installation of the ailerons. In fact, we see a slight increase in corrected performance data, a drag reduction we cannot explain.

In summary, the current configuration (canard elevators for pitch, conventional rear wing ailerons and no spoilers) gives the airplane overall flying qualities we can all be proud of. Roll rate is more rapid than the average light plane, adverse yaw is much less, and flight safety for first-flights/pilot transitions is improved. Those of you who had already fabricated the spoilers and the old configuration stick assembly will have a mild setback in $ and work, but the result is well worth the additional effort. We feel concerned enough about the problems some homebuilders encountered with elevons that we are recommending that inspectors do not approve a VariEze for an airworthiness certificate unless ailerons are installed. The out-of-trim condition on first flight has not yet caused an accident and we want to insure that it never does.

COMPOSITE STRUCTURE DESIGN We receive an occasional question concerning design information and materials properties on composites. An excellent reference is a series of articles written by Hans Neubert and Ralph Kiger published in "Sport Aviation" (EAA) Magazine July 76, Sept. 76, Dec. 76 and April 77.

VARIEZE ELECTRICAL SYSTEM As you know from newsletter 12, we have been testing an electrical system that does not need the engine's alternator. We are doing this to alleviate the tail heavy condition caused by use of the heavier engines: 0-200 and Lycoming 0-235. N4EZ has been flying since January without the alternator and with a trickle charger for overnight charging. We added a backup battery and a solar cell panel in April. Since the solar panel has been added we have not used the trickle charger. We have powered the electrical system only with the sun. The electrical system has one NAV COM, engine instruments, gear warning horn, and one turn-and-bank gyro. The diagram below shows the electrical system now installed in N4EZ. The main advantage is that it keeps all the weight forward, a necessary requirement for the heavy engines. The solar panel is more reliable than an alternator/regulator system. For normal use (see newsletter 12, page 3) the panel supplies more than enough power even if the airplane is hangared. If extended flying is done under cloud cover or if radio or gyro use is higher than normal, the airplane can be plugged into any 110V AC outlet overnight to top off the batteries.

We are using an off-the-shelf solar cell panel as shown, purchased from Edmond Scientific Corp. This panel is made to be bolted on a roof and take all wind loads and is thus too thick and heavy (0.3" and 2 lb) for our application where the panel is bonded to the skin over the instruments (see photo). We have written to three solar cell manufacturers, asking them to build a panel on a thinner back plate for this application. We have not yet received an acceptable offer. In addition to the diode supplied with the panel we added one in series to

cut the battery drain in darkness to less than one micro amp. Thus, a switch is not necessary to turn on only when in daylight, the panel is on all the time and charges whenever daylight is available. Unfortunately we do not know the designation of the diode we installed. We tried several from a miscellaneous box sold by Radio Shack and selected one (unmarked) that provided less than 1 micro amp dark drain, while allowing full charge in sunlight. Hopefully one of you reading this can determine an available diode spec and let us know how to call it out. Send the diode so we can check it out.**SKETCHES OMITTED**

Stan Sigle sent in an improved wiring diagram for the warning system in section III. This system uses the same switches, just rewired. This prevents the gear horn from honking during nose down parking with the master on. It also warns you to not prop the engine if the throttle is open. Normal function of canopy-open warning and gear-up warning is not changed. Thanks, Stan. **SKETCH OMITTED**

VARIEZE EXHAUST SYSTEM As we told you in a previous newsletter, we have been experiencing failures with the exhaust system in the VariEze. These failures show up as cracks in the tubes, generally at the first bend or flange. Since we were using only mild steel automotive exhaust pipe we thought that going to a stainless system would solve the problem. We tested an identical system fabricated with excellent workmanship from type 321 MILT 6737 stainless. This system had failures in two of the tubes within only 12 hours flying! A materials problem is thus ruled out. We have found that the problem is that of resonance - the pipes are of such a length that they vibrate in harmony with the engine and result in fatigue. This is quite common with new systems. We are taking two approaches to solve this problem. The first has been on N4EZ for the last two months, the second is being fabricated and will be tested when available.

1. Shorten the tubes to raise the natural frequency to eliminate the vibration. The left-front tube has been modified as shown. Its 6.5 inch length has been completely wrapped with a spiral of overstretched screen door spring. A simple carb heat muff is made from scrap from your firewall stainless material. This muff is a cylindrical flange for the carb heat hose and a sheet that wraps around the spring-wound tube. The muff is held on with two springs which snugly hold it on to avoid vibration. Carb heat air is drawn in from each end, over the spring coil and into the flange/hose. The other three exhaust tubes are 7-inch straight stacks, exhausting straight down out of the cowl. The advantage of this system is that it's light, cheap and should solve the vibration failure problem. Its disadvantages are that its loud, and cooling air is lost around the clearance holes for all four tubes. Also, it is possible that these stacks are short enough to cause a valve cooling problem, although we have seen no indications of this yet. **SKETCHES OMITTED**

2. Develop a quiet muffler system. The vendor that fabricates the system for the Cessna 152 has designed and is now fabricating a compact stainless dual muffler system. It will be quiet and will exhaust aft, such that it will not result in loss of high pressure cooling air. It will require a minor cowling modification involving adding two blisters to the existing cowl. Yet to be determined is, of course, if it will have adequate life in service. We will be doing considerable flying once it's installed to answer the question as soon as possible.

Now, for the big question--what should you do with your exhaust system if you have fabricated it to the dimensions of section IIA? We recommend that you immediately modify it, cut it down as described in 1 above, or at least shorten the horizontal members to 6" or less. This requires four new holes in the lower cowl and patching (4 plies BID) the existing holes. If you are flying the long tubes, carefully inspect them for cracks every five hours until you make the modification. If a tube completely fails and falls off in the cowl, the possibility of engine failure or fire may exist. Do modify your tubes. One EZ owner had cracks in only 25 hr flying.

COMPOSITE STRUCTURE We have received a couple reports from builders who conducted static tests without knowing the correct method. One builder set his canard tips on two chairs and jumped up and down in the center. He assumed that this could not overstress the canard since the load data indicated it could take four people on each side. He assumed wrong. The bending moment curve in newsletter 10 was greatly exceeded at b.l. 50 where he showed an indication of failure. If you are going to do a static load test assume nothing. Check carefully the loaded bending and shear data. Never apply loads dynamically unless you have means to measure the dynamic load component. Never apply more than 20 pounds per square inch load on any surface with less than four plys skin thickness.

We recently conducted a series of tests to compare shear strength and peel strength of laminates with a variety of glass surface preparations: wet layup, dacron peel ply, dull sand, half dull sand, and no preparation. Test results support our recommendation to use peel ply wherever a glass layup will be done over a cured glass surface. The additional strength obtained by sanding a surface completely dull does not justify strength loss from removing the top ply to do so. A peel-plied surface or a sanded peel-plied surface is best. Full strength of the original surface is maintained and the itch and work of sanding is avoided.

A recent article stating that one drop of fiberglass resin catalyst in the eye will destroy the eye tissue and result in permanent blindness. The material they were discussing is MEKP, which is a catalyst used in polyester resins, none of which are used on the VariEze. The hardener used in our epoxy resins should be used with appropriate precautions, but does not have the tissue destroying characteristics of the highly toxic MEKP.

From the information we have been receiving about 70 to 80% of you builders have no reaction to working with the epoxy. About 15 to 20% have a mild reaction such as mild skin rash if skin is not protected or shop not well ventilated. About 5 to 10% have more severe epoxy sensitization, some cases very severe. Those with severe sensitization should not be working with epoxy. The important thing to remember is that the effects are accumulative. If you have no reaction you should still use ply 9 or gloves and good ventilation, since your system will build up to the point where you eventually will become sensitized. Do not be over confident and work with bare hands.

Owens Corning has published some test results of E & S type fiberglass applications for Boeing helicopter rotors. "Our tests show that the loads on a metal blade can cause a barely detectable crack to propagate to catastrophic failures in a few minutes--but because of the materials elasticity and its ability to provide alternate paths of stress, crack formation and propagation are virtually nil with glass composites"---we shot both a metal blade and a glass blade with 23mm shells. After 60 hours the level flight plus maneuver tests the glass blade showed no signs of damage propagation but the metal blade fell apart in three minutes"---"other reinforced composites have not proven as failsafe as glass. For example a bullet hole causing a 5% loss in area will cause a 5% loss of strength in a glass blade, but will cause a 32% loss in a graphite blade and a 43% loss in a boron blade." In 1976, 24 million pounds of glass composites were used in aviation--not including 150,000 pounds for VariEzes!

PROPELLOR EFFICIENCY/VARIEZE PERFORMANCE Propellor efficiency is a concept that confuses the average pilot. This confusion is evident in a lot of the questions people ask us. Molt Taylor's propeller article in the May 77 Sport Aviation magazine contained some misleading and incorrect information that has added to the confusion. While it is true that it is impossible to fly faster than the theoretical helix formed by a propeller, you cannot calculate an airplane's maximum theoretical speed from rpm and the pitch value stamped on your prop. The reason is that most prop manufacturers use the flat bottom of the blade as the pitch reference rather than the zero lift line. On a typical high speed prop of say, 70-inch pitch, the actual theoretical pitch measured at zero lift of the blade section may be as high as 79 inches, and will vary along the blade according to the prop designer's method of twist distribution to load the blade the way he wants. Propeller efficiency is, by definition, thrust horsepower obtained, divided by brake horsepower input, and has no direct relationship to helix slip, as inferred in Molt's article. It is common to obtain values of negative slip as high as eight to nine percent at high speed with any low drag airplane, using propeller manufacturer's pitch values, for example: using a 67-inch pitch Cassidy prop on a VariEze at 9000 ft at 65% power and 2650 rpm, the calculated prop helix speed is 168 mph, but the airplanes true speed is 180 mph. At this flight condition, the prop efficiency is not 107% as inferred by Molt, but the technically correct value of 84%. If the airplane's drag were doubled, the "slip" would go from 107% (180 mph) to about 83% (140 mph) and the prop efficiency would drop from 84% to about 73%.

Since we had printed the rpm vs. airspeed data in newsletter 12 we have found that the tach in N4EZ is not producing accurate readings. We recently tested a new propeller and before making conclusions on it we retested two of the previous props. The data did not agree with previous data. We do not know when the error occurred so we must suspect that the newsletter #12 rpm data may be wrong. We will update it when we get our tach calibrated.

We have recently done performance tests with the Jiran wheel pants installed. We have had some difficulty defining the exact performance gained due to some conflicting results in the corrected data. Averaging these it looks like the wheel pant increment at 75% power (full throttle at 8000 feet altitude) is approximately 5 kt (6 mph).

This is less than our earlier estimate of 7 kt (8 mph). We have noted what appears to be a 3 mph decrease due to removal of the spinner.

With pants, N4EZ will indicate 150 kt (173 mph) with full throttle at 8000 ft (75% pwr, approx. 2830 rpm). This is a true airspeed of 169 kt (195 mph). At 3000 ft, full throttle true speed is 173 kt (199 mph). These speeds are about 5 kt slower than the data in the Owners Manual, due to a number of items; protruding solar panel, left trimmed rudder, canopy airleaks and exhaust system. The speeds are lower than we expected, but it is still possible for an optimum VariEze to get 200 mph at 75%--Anyone want to race?

Recently checking some more of the Owners Manual data we have found N4EZ capable of exceeding the rate of climb data at high altitudes and somewhat less rate of climb than the book at low altitudes. Takeoff distance data at high density altitudes (7000 ft) is identical to the Owners Manual.

Other performance data for the low horsepower engines obtained by calculating the static rpm for a 65 hp engine then setting a throttle position to obtain that rpm. Then flight tests were performed at that throttle setting to estimate 65 BHP performance. In general, the Owners Manual data for 65 BHP was confirmed. We had a race with Fred Woodbridge's Xenoah - powered BD5 and found that we had less takeoff distance, better rate of climb and faster top speed than him, while using only 65 BHP!

VARIEZE WEIGHTS One of the biggest disappointments of the VariEze development has been the continual weight growth. The original prototype N7EZ, which used a 140 lb engine had an estimated empty weight of 385 lb. When N7EZ made its first flight its empty weight was 399 lb. Now, after some modifications, addition of electrical system (radio, gyros, etc) its empty weight is 460 lb. When we originally designed N4EZ for a 173 lb Continental A-75 engine, its estimated empty weight was 480 lb. After incorporating a lot of items demanded by the average homebuilder, adding weight to ease construction in several areas and adapting the 205 lb 0-200 with alternator and complete electrical system, N4EZ made its first flight with an empty weight of 570 lb, including an extra heavy paint job. At that time we anticipated that a prudent homebuilder without electrical system could build it as light as 535 lb. N4EZ now weighs about 585 after all its developmental modifications and after removal of alternator.

Our current disappointment is finding that too many builders are loading their airplanes down with extra equipment and heavy finish jobs. They are going to miss the real thrill of flying their EZ at a light weight, and they will find their useful load disappearing. Here is the trap--if you address each item as "Oh, that's only one/half pound, it's a small percent of the empty weight," you will find that the sum of all the extras will add up, and when you weigh your ready-to-fly airplane you will be scratching your head and saying, "where is it all?" Believe me, it happens every time.

We have a strong recommendation for all of you, and that is to delay installation of any equipment not absolutely required for flight, until after you have flown your airplane a few hours. Then, you will have a much better chance of a successful flight test program--the airplane is easier to fly light and uses less runway. Also, if you make a real bad landing during your transition it will put a lot less stress on your landing gear. Then, if you must, load on the equipment, at least you will get to see first-hand the effect it has on performance and runway requirements.

This philosophy also goes for modifications, too. Don't try something new on your unflown new airplane. Build to the plans first, where you know from our experience that it will work. Fly it that way, then try your modification.

VARIEZE FUEL SYSTEM We continue to be pleased with the three-tank fuel systems operation. Its configuration allows you to use all the wing fuel in level flight and all the fuselage fuel in any normal altitude, as well as give you an extremely accurate indication of the last few gallons. This really takes the apprehension out of a situation where you are stretching the range with low fuel. Be sure you are installing the system as shown in newsletter 11, not the original from section IIA. Also, note the operational comments in newsletter 12, page 5.

As you know, the wing tanks must be vented together to keep even fuel levels. Last month I fueled N4EZ then took off after installing only one fuel cap--I forgot to put one on. In flight, the pressure over the cap hole is very low--this caused all the wing fuel to be drawn into the tank without the cap. After about one hour airborne, all the fuel had been sucked out of the other tank (and the line) and the engine quit. I selected the fuselage tank, got an immediate restart and flew home. With the old system (no fuselage tank) I would have had a forced landing. We have added a visual check of the caps to the takeoff checklist. They are easily seen from the cockpit.

We recently learned that the black polyethylene fittings used in the fuel system are not recommended for use with fuel. The manufacturer recommends PVC or white nylon. The same fittings are available in nylon, so we replaced the ones in N4EZ with nylon. The black polyethylene ones have been in fuel in N4EZ for almost a year with no apparent degradation, so it doesn't look like an immediate problem, but you should replace yours with white nylon next time it's convenient to do so. Aircraft Spruce, Brock, and Wicks now carry white nylon. The affected parts are 0715-020 tee, 0710-162 elbow and 0700-162 adapter.

VARIEZE PLACARDS We have noted that several of the VariEzes we have seen are not adequately placarded. All cockpit controls and switches must be labeled. In addition, we recommend the following information. A convenient placard can be made using small rubon letters (stationary store) on white card-stock, protected with a coat of clear epoxy.

Radio call NXXXX
Maneuver speed 120 kt (140 mph)
Gear actuation speed 85 kt (100 mph)
Max landing brake speed 90 kt (105 mph)
Max front seat pilot weight XXX lb
Min front seat pilot weight XXX lb

```

```

VARIEZE ENGINES N4EZ, except for the exhaust system, continues to be free of any non-routine engine maintenance. The latest AD on all 0-200's (timing change) was complied with. The only input on engines from homebuilders has been two instances of higher-than-normal cylinder head temperatures (over 400 degrees F). If yours is running over 400 degrees, check for baffle leaks. One builder reported temperatures reduced after 10-hours flying. This is common for newly overhauled engines.

By the time you read this, one or two Lycoming 0-235 EZs may be flying. If they prove successful, RAF will market installation drawings for this engine ("Section IIC") possibly as early as October.

VARIEZE BUILDING HINTS We continue to be asked questions about construction methods that have previously been outlined in newsletters. It is suggested that you note the building hints from all newsletters into the green section of your plans in the appropriate area. Thus, all of this educational material will be in one place for you to review occasionally. It is a good idea to reread the green section every month or so during your construction project to assure you don't forget an important method or hint.

Again, thanks for the hints turned in by you builders--be sure to send a self-addressed stamped envelope along with your suggestions so we can comment on your ideas.

Probably the most troublesome step in the EZ construction has been wings, step 4, page 6-5. There have been a few problems in several areas: 1) it's a long tiring job, ending in an important alignment of several pieces, 2) it covers some glasswork immediately, making it impossible for FAA inspection of vertical shear webs, 3) some builders have not been successful in making a uniform correct thickness layup on the pads in the wing fitting area and have found that they later did not have enough room for the spar cap and skin under the top plate. We are now recommending two improvements that should make this step VariEze. First, layup the 12 and 15-ply BID pads separately. Do this as follows: lay Saran Wrap on a flat surface, layup (RAES) 1 ply Dacron peel ply, the 12 or 15 plies BID and another ply Dacron peel ply. Cover with Saran Wrap, place a flat block of wood or aluminum and load or clamp with about 50 pound force. Let cure. Trim the cured pads to fit the wing fitting, rounding the edges to allow a smooth shear web layup. Peel the Dacron and bond the pads in place. Be sure they fit flush to the adjacent foam surface. This will assure a straight spar

and a pad that is not too thick. The second method change we are recommending is to split step 4 into two separate cures. Stop at the bottom of page 6-5. Peel ply all sides of the box spar. Lay Saran Wrap on a flat surface and set the box on it being sure it is straight while it cures. After cure, peel the Dacron, drill holes for the dowel jigs (see newsletter 12, page 8) and continue with the jigging operation on page 6-6. At this point the aileron cores have been removed from the inboard trailing edge core. Place them back in and hold in position with nails so you will have the straight trailing edge to align the cores in the jig. In summary, an important step has been changed from a long difficult one to three relatively easy ones. Do use the separate-weighted cure method on the four thick pads in the center section spar also--this will avoid a high buildup there.

The lower bolt that holds NG15 to the fiberglass strut must be positioned as shown on page A7. If it is placed in the center of the strut the strut can be split under load. Be sure to use the BID plies here (CP #11, page 4).

Some have complained about having to remove the canard to service the battery--you're right. I'd suggest moving the canard cover joint aft as shown and add an access panel. The hole should be done similar to the hole in the rear seat bulkhead. The door can be a piece of .025 2024 T-3 aluminum using six #10-32 screws or four camlocks. You might even want to reverse the canard lift tab bolts so they can be reached through the new hole--it takes a long arm to reach them through the cockpit. **SKETCH OMITTED**

Several builders have asked how to repair a poor trailing edge overlap in the canard, wing, or winglet. The method shown below works quite well. The surface is prepared for bond, the dry BID cloth at 45 degrees is taped to one side, wrapped to the other side and taped snugly to pull out wrinkles. Once it is taped down well the BID is wet out with a brush (RAEF) and allowed to cure. Remove the tape (gray duct tape works well) and fair in the edges with 36 grit sandpaper. This method can be used full span on the wing for a super strong trailing edge joint, with a small weight penalty. It is not considered mandatory, though. **SKETCH OMITTED**

CP13, Page 5

It is possible to install the Cleveland brake torque plate assembly incorrectly on the outside of the axle. This will bind the brake. Install it the correct way as shown below. **SKETCH OMITTED**

One builder has suggested using carbon paper to trace a reverse pattern of the templates for the opposite side patterns needed. If you use a copy machine to do this, check for paper shrinkage.

The fittings from Brock have a slightly scored finish on the edges due to the punch operation. Use some 100 grit emery paper to polish these scratches out before installation.

A close study of the cross-section drawings in section V will answer a lot of your questions on finishing.

A Sears #93987 Angle Finder is handy for rigging control surface travel and many other jigging operations.

Another material that works well for hot wire templates is Masonite. Sand the edges smooth and lubricate with pencil lead. The hot wire will slip over the graphite with ease.

Do not use paint removers on an epoxy surface.

Layup time can be excessive if epoxy is only 5-10 degrees cool. Keep epoxy at least 75 degrees for best results--one builder stores resin in a cabinet with a light bulb on.

The nose bumper can work loose due to flexing of the nose gear strut. We have it mounted to the fuselage skin with extra BID plies, immediately forward of the gear, directly under the NG31 bulkhead.

Some builders report that a hot-glue gun is handier than the Bondo in many jigging operations. Also, a pair of electric scissors works well in cutting dry glass cloth.

The Westach RPM gauge wiring works as follows: black to ground, green to magneto and red is unused.

Check the length of the AN509-428-16 screws before countersinking the wing fittings. You should leave the heads a little high, not flush. Better yet, use the AN525's and do not countersink.

You may have trouble with the foam tabs on the main gear bending when you install the glass and clamp. You can substitute 1/4 inch plywood for the foam to prevent this. Do not be concerned about shaving some material from the leading or trailing edge of the gear strut to install the 25-ply outside pad. This will not weaken the gear. It's more important that the pads be laid up straight and not made undersized.

Many builders who previously were taking several times the man-hour estimates, now report they can beat the times, when using all the hints in the last several newsletters.

Truss connector plates--gang-nail devises that secure boards of wood house trusses, make perfect securing devices for foam blocks. Use them to bridge two blocks of foam or shove them into a single block and tie string to it to pull it up to another. Thanks, John Carroll.

Canopy locks must be installed in the correct alignment and engage fully in the positions shown on page 22-10. Adjust so the handle must be forced hard forward to engage the lock while firmly squeezing the rubber canopy seal. This prevents the locks from wearing due to rattling and prevents the canopy from locking when it is closed from the outside. I installed a "drawer lock" ($1.69 at any hardware store) in the fuselage side so I can close the canopy and lock it from the outside with a key. The drawer-engage tab is replaced with a longer aluminum arm shaped to engage the center canopy lock bolt in the closed position. We are using the low density foam rubber weather stripping for a canopy seal. This is the real light material that is about 1/4 inch thick but easily squeezes flat.

If you insist on a capability to open the latched canopy from the outside, install a door on the fuselage side aft of the canopy latch. Wicks did this, and included a key lock in the door.

We have received several comments that the return spring at the rudder is too strong. It is possible that if the hooks are installed short this spring will be far too tight. The only requirement for this spring is to return the rudder to neutral on the ground. Inflight airloads firmly return the rudder. The spring can be lengthened or a lower-rate one substituted. It only needs to be firm enough to overcome friction of the system and the rudder pedal spring. We have selected three different screen door springs available at our local hardware store. The dimensions and spring rates are shown below.

	Outside dia.	Wire dia.	Lb/in for 1" length	Max. force
#1	0.30	0.045	31	20
#2	0.35	0.05	38	30
#3	0.39	0.62	50	35

For the rudder return spring you can use either a 4-1/2 inch length of #1 or a 5-1/2 inch length of #2. Both of these have a spring rate of 6.9 lb/inch.

For the elevator trim the upper spring is a 9 inch length of #2, spring rate = 4.2 lb/in. The lower spring is a 13 inch length of #2; spring rate is 3.0 lb/in. If you substitute another spring, be sure to match the approximate spring rate. All lengths mentioned are unstretched length.

R. Godle has turned us on to an epoxy layup roller that works much better than the one suggested earlier. This one has no tendency to lift the cloth and has an excellent stippling action for working out air--we use it on any major layup now. It is called a "3 inch adhesive cover" available at Standard Brands paint stores--stock number 430051, manufacturing number SC251/3V95.

Clarification--the canopy cross brace goes under, not thru, the plexiglass. The plexiglass has no holes on a VariEze installation.

A plywood or metal block bonded to the bottom fuselage skin where the speed brake push rod strikes the skin, will prevent deterioration of the skin edge.

A plywood square mask as shown in the sketch slipped over each end of the centersection spar (step 2, page 8-2), will hold it perfectly square during cure. **SKETCH OMITTED**

In areas where the thickness of glass buildup is important - shear webs, spar caps, pads, etc. - always calculate the thickness (0.13" per ply for BID, 0.009" per ply for UND) and measure the foam core to be sure the foam is the correct size before glassing. The spar cap and skins must make a smooth, straight transition onto the outboard cores (wing and canard). Be sure you fully understand the quality control criteria in "Section I," "Section V," and newsletter 10.

VARIEZE PLAN'S CHANGES We still receive questions regarding changes that have been printed in the newsletters. Be sure to write all plan's changes into your plans, otherwise you may forget and skip them later.

Checklist	Add "check fuel caps" under takeoff checklist
Section I, page 6-5	Photo at top is misleading--method is correct but the part is shaped different--it was from N7EZ.
Newsletter 11, page 7	On the second 22-8 change, the AN509's should be AN525's.
Newsletter 12, page 11	After "ailerons as shown" add the word "below."
Section I, page 22-10	The solid line on the lower drawing of C-7 should be dashed.
Aileron Addendum	6061 T-6 can be substituted for the 2024 T-3 on the 3/4 inch tube.
Section IIA	Modify exhaust as shown in this newsletter
Newsletter II page 6	Add "white nylon" after "Ryan Herco 3 places

---

The following Owners Manual revisions were included in the Aileron Addendum to update the manual for an aileron-equipped airplane. They are repeated here so those non-builders that have section IV can get it updated.

Owners Manual Changes For Aileron-Equipped VariEze

Page 7 & 8	Strike first three sentences under Control System Add "Pitch is controlled by a full span canard slotted flap providing a large allowable Cg range. Roll is controlled by conventional ailerons on the rear wing.
Page 8	After the fifth sentence of Trim Systems - Add "The roll trim system is optional."
Page 13	Strike the following - "If it's a strong crosswind .....the wings."
Page 14	Under "Climb" - Add "The VariEze's excellent sideslipping characteristics allows the pilot to sideslip left and right for required forward visibility during steep climbs.
Page 16	Add "Sideslips can be done on final to lose excess altitude.

Strike the following - "At pattern speed.....
right at home."

Strike - "Your separate surface.....corrections
and maneuvering." Change "third method" to
"another method".

Page 18 Strike the second paragraph. Add - Ailerons and
rudder are effective at all speeds including
full-aft-stick flight."
Strike the last sentence. Add - "Sideslips can be
done at any speed down to and including full aft
stick speed."

Page 24 Strike - "A pilot who flies only.....gust during
the landing flare.

Add - "The VariEze has entirely conventional
flying qualities. However, its landing speed is 5 to
15 knots faster than most light planes and should
not be considered as a training airplane to develop
basic flight proficiency."

Strike - "Once on the ground."

Strike the last paragraph.

Page 28 Modify the allowable cg diagram as shown. Note
that when the canard is used only for elevator the
allowable forward cg is greater. This supersedes
the change shown in Newsletter No. 12. **SKETCH
OMITTED**

Page 29 Change "and elevon" to "elevator and aileron".

Strike - Elevator Travel Section.

Add - "Elevator travel 22 degrees +-2 trailing edge
down and 20 degrees +-2 trailing edge up."

Add "Ailerons must both fair into wing at
trailing edge when neutral. At full deflection
aileron T.E. must travel 1.9 "+-0.3" at outboard
end (measure relative to wing T.E.)"

Page 30 Change "elevon" to "elevator and aileron" (four
places).

Page 40 Change "elevon" to "elevator".

Change "pushrods" to "pushrod".

Page 43 Add "aileron modification complied with."

Note: The ailerons make no discernible change in performance.

EZ PROJECT FOR SALE We regret to report that EZ builder A.C. Boyles, a professor at Glendale College, suffered a fatal stroke while teaching. A.C. was a capable and well respected EAA designee in the Van Nuys Chapter. A.C. had nearly completed his EZ and his wife, Lucille, now has it up for sale. Price is $12,000.00 including an OSMOH perfectly balanced A-75 engine. The workmanship is superb on this project. Write Lucille Boyles, 15249 Dorian Street, Sylmar, Ca. 91342.

QUESTIONS/ANSWERS

Q: Can you give me the names of those near me building an EZ or VariViggen?
A: No, we do not have the permission of plan's holders to include their name on a public list. Attend your local EAA meeting and ask who is building. A list of EAA Chapters can be obtained from EAA, Box 229, Hales Corners, Wi. 53130.

Q: How many EZ's are under construction?
A: Approximately 1000, worldwide.

Q: What back issues of Canard Pusher do I need if I'm building an airplane?
A: Ten through current for VariEze, one through current for VariViggen.

Q: Now that the canard is used only for pitch can I shorten it or use a plain flap instead of the slotted flap?
A: No, changing canard area would move the allowable cg range. The high lift with the slotted flap is required at forward cg. The canard is your main wing, carrying about 25 lb/square feet at forward cg.

Q: What type of respirator is recommended to filter epoxy fumes and foam dust?
A: According to the Mining Enforcement and Safety Administration of the Department of the Interior you should select an approved chemical cartridge respirator. Manufacturers are MSA, Welsh, Willson, Scott, American Optical Corp., 3M, Binks, or Glendale Optical Co.

Q: Since the basic bill-of-materials, page Z-Z of Section I has undergone several revisions can I get a revised one, including all newsletter and aileron changes.
A: Yes, it's in this newsletter.

Q: Looking at the CP 12 data it looks like the Cassidy prop is 10 mph faster. If this is true, why are you now flying the Ted's prop? A: Many people including you have misinterpreted this data. N4EZ's maximum speed at full throttle is the same with both these props. The Teds merely allows the engine to turn faster. The Cassidy prop has a little better efficiency at top speed, since the same speed is obtained at slightly less BHP. Since the Ted's prop turns more rpm at low speeds it allows more horsepower to be available for takeoff and climb and thus T/O and climb is a little better. The reason I use the Teds is that I rarely cruise at 75% power and don't mind using 2850 rpm to do so. Due to the small diameter prop the tip speed is actually less than with a Cessna at a lower cruise rpm. I generally cruise at 50% power which is a low manifold pressure, but medium rpm, about 2550. The fixed-pitch prop for a fast airplane is a compromise, designed as a

climb prop to give adequate takeoff performance. Remember that to get 75% power (75 BHP on an 0-200) with a climb prop, you must do so at a higher rpm (lower manifold pressure) than you are used to on your slow light planes. Your engine develops 75% power at full throttle at about 8000 ft.

DISTRIBUTOR STATUS - VARIEZE MATERIALS

Aircraft Spruce and Wicks - Essentially all items are currently in stock. Expect backlog on wheels and brakes. Aircraft Spruce can supply a walkin/pickup order with three-days notice.

Jiran - Immediate delivery on COWL; five weeks on wheel pants and fuel tanks; eight weeks on landing gear and mounted canopy. The unmounted canopy frame is no longer available. When requesting Jiran catalog send SASE with three-ounce postage.

Brock - '77 catalog is now out. Landing brake and all aileron prefab parts are now stocked. Brock's backlog is rapidly improving. His backlog was over 10 weeks on some items. It is presently about six weeks. Over 100 nose gear assemblies were shipped the first week in July.

Cowley - Canopies are available on immediate delivery.

CP13, Page 7

VARIVIGGEN

VARIVIGGEN PILOT CHECKOUTS As we mentioned in CP 12, N27VV was being made available for pilot checkout of those who have a Viggen nearly completed. We have had three builders come by for this purpose. In each case, we asked them to carefully read the information given in the Owners Manual and newsletter, then give us their comments after the checkout with emphasis on any information that should be passed on to other builders. All three practiced flying from the back seat including pitch control during rapid throttle changes to get used to the trim change. They then got in front and conducted runway flying tests outlined in the Owners Manual and then flew pattern flights. Their comments follow:

Mike Melville - "Burt made the first takeoff and one of the lasting impressions was the sight of the shadow following along in the early morning sun.

Burt demonstrated level flight, slow flight, turns, steep turns, and most important, pitch trim changes with abrupt power changes. This is something that has been emphasized over and over and rightly so. It is an unusual condition, but to be perfectly honest, not a difficult thing to get used to. Personally, I had very little problem with it, however I was thoroughly aware of the condition and I am very current in several different aircraft. This is a point that cannot be too strongly emphasized.

Any person thoroughly checked out and confident in say a Cessna 182, a Grumman Tiger and a tail dragger, in my case a homebuilt Nesmith Cougar, will have no problem with the VariViggen.

After a little stick time in the back seat, we traded seats and I spent quite a while just taxiing the airplane all over the place and let me say this, there cannot be a more simple or manageable airplane anywhere. It is so easy to drive around on the ground and it goes right where you point it, marvelous!

Then I did some high speed taxi runs, again, just point it and go, no problem with keeping it on the centerline, it tracks perfectly straight, and the rudder becomes effective very early in the takeoff run.

Next we tried some nose wheel liftoffs. This must be done in accordance with Burt's instructions in the Owners Manual. Get it stabilized at the speed you want, retard the throttle, then rotate. The nose will come up and is very easy to control. I want to emphasize, pitch control is excellent. Before I tried it, I was worried that pitch control may be marginal. However this is not so at all. Pitch control is really great, you can put the nose anywhere you want to and maintain it there.

Then we did a couple of runway flights, liftoffs and flying in ground effect. Again, control is excellent, both pitch and roll, and I felt very happy in it. Full power takeoff was an anticlimax, it was very normal and flew just like any other high performance single engine. Handling qualities in the air are great. It flies perfectly in my opinion, in fact I was very pleasantly surprised. It is all I had ever hoped for and more!

The landing, again was almost anticlimactic, with the correct airspeed and altitude, it will land itself. The only thing to remember when landing is not to try to full stall land it as you would a Cessna. It is much better to fly it on, the gear is very forgiving and takes care of most bumps. Don't try to hold the nose gear off right down to a virtual stop, because it will stay up until the canard quits flying and then will fall through rather abruptly. This is no problem, but I personally think that you get a nicer landing by letting the nose down before the canard quits. Also, this gives you better braking, as all the weight will be on the wheels instead of some of the weight being carried on the wings, which it would at the high angles of attack, possible by holding the nose off.

If you try to stall it on, it is possible to hit the tail skids on the runway, so until you get really familiar with the airplane, listen to Burt and fly it on!

To recap: make sure you read and fully understand the Owners Manual on test flights. Then go out and enjoy your Viggen, it is a super airplane."

Burt's comments: Mike is a very proficient pilot. He handled the airplane in the first few seconds like he had 100 hours in it. I particularly noticed how well he flew the rudders-- must be his Cougar

experience. Mike should feel right at home and confident on his first flight in his Viggen.

Charles Allen - "Would like to offer some candid observations on my first flight in N27VV. They are designed, hopefully, to benefit other builders. Also, I hope, of some use to you.

I waited to write until I'd had a chance to fly the G.A. Trainer again, which I did today, and go through some of the maneuvers and fast power changes we made in the VV. I have also read the Owners Manual and found it excellent and complete. Can't find much to add, but after a vivid first impression of the VV, would like to underline a few things.

The first and most important question in a builders mind is, how is a VV different in flight from a conventional small plane, such as the Grumman American Trainer? There is one big difference, and it is explained well in the Owners Manual under "stall characteristics." But I think this difference is so important that it should be spelled out, and emphasized again and again. The difference is that there is a completely opposite pitch-trim change from that in conventional planes, and it is much more severe. Put simply, there is a definite nose pitch-down when power is added, and a definite nose pitch-up when power is reduced. The severity of these pitch changes is proportional to the speed with which power changes are made. Therefore, smooth and gradual changes in throttle settings are essential, especially at low airspeeds. And especially during early liftoffs and flight testing. The elevators are quite capable of correcting these pitch changes, but the pilot used to conventional aircraft could easily be caught by surprise, and not correct promptly. Again, the potential VV pilot should commit this concept to memory, and be alert and mentally prepared when starting out on those first liftoffs.

Another strong first impression I had from both the back seat and the front seat, was that a "high angle of attack" does not seem very high. Therefore, I had a tendency to get into a nose-high full stall attitude when landing. A flatter angle, quoting Burt, is safer and better to use.

Have a few more random impressions of first VV flight.

It is really a thrill to look down and see, for the first time, that wedge-shaped shadow following along!

It's true, handling and maneuverability are exceptional. It can be turned on a dime. Visibility is outstanding.

Landing gear operation was very smooth. I noticed little difference in trim. The gear feels quite firm and solid on touchdown. And speaking of landing gear, the VV has the greatest ground handling qualities that I can remember, and I date back to WW II. It is a firm, stable, easy to steer, and has perfect visibility. A real fun airplane.

Engine noise seemed less than in conventional planes, tho I am not sure of the facts. The Lyc. 0-320 responded smoothly and reliably to all kinds of power changes during the flights and on the ground.

Burt's seats didn't fit me too well, but I think seating is an individual thing and must be worked out to each builder's satisfaction.

Though the VV and I are hardly acquainted, I think it's love at first flight--and I'm glad I'm building one."

Burt's comments: Charles handled the airplane well and was able to fly it straight and level during rapid power changes after only a few seconds practice. I'm confident he would handle his Viggen on his first flight with or without his experience with N27VV.

Harold Reiss - "Decided not to go to see Jim at Phoenix, but rather to head on home and get some work done on 29 HR. I think I'll try to get it ready to fly in prime paint only by the end of July and maybe you'll have some time to come by Urbana, after Oshkosh, and try it out. If not we'll see who does first flights later on.

Thanks very much for your time and for the use of 27 VV. It was a real eye opener for me, though I don't feel it is quite as difficult to fly as I led myself to believe, just different in pitch due to power changes. I do feel that it is easy enough to counter if you don't get into a difficult situation such as an emergency go-around before you become accustomed to the reverse pitch change. In a case like that each one of use builders had better be on his toes.

The biggest problem I had, in my opinion, was the high angle of attack during landing. I think this was due to two things. One-the forward visibility, with no engine or prop in front of you, is much better than the average light plane can offer and so gives little to use for reference during landing approach. Two-most pilots were not taught to drive an airplane onto the ground, myself included. It's hard to feel that the nose is still high enough due to that forward picture. However, practice in the VariViggen will overcome this difficulty I am sure.

Each builder who plans taxi tests and first flights should, as you said, get good as well as current in several aircraft types. A stick rather than a wheel and conventional gear rather than tri-gear would be best. (I was just barely current in the Arrow and had flown 6 or 7 hours in the last year, besides the trip to Mojave). Ground steering is excellent and low speed during takeoff is about like a 140 Cessna, though a bit easier.

I think your rudder system in 27 VV leaves a little to be desired, as it was very hard to feel the amount of rudder applied I think the plans built will be much better because of the spring loading at the front rather than the rear pedals, and because does not have those centering bars. I used rudder but apparently not enough--it seemed as if the pedal got hard after about 1/2 inch of movement. I guess the Arrow with its auto pilot lets a person get somewhat rusty. I have started to clean up my flying and next time I assure you it will be better."

CP13, Page 8

"I do feel that I can get along with the Viggen well enough to start learning the airplane. I would advise all builders not to get into the

airplane, with testing in mind, without a thorough checkout from someone who has become accomplished in a VariViggen. I hope you will emphasize this fact in future publications so that we do not have any bad situations in the future."

Burt's comments: Harold's limited flying experience in the last year did show up in that I had the impression that he was not using the rudder pedals and was letting the airplane stray quite a bit before correcting in pitch. It's difficult for me to speculate how well Harold would do on his own first flights. I did help him some on his first couple of landings. I recommended that he get Mike (who lives nearby) or me to help him on his first flights unless he gets proficient in several other airplanes. While he probably would do fine, mixing probable with the other unknowns possible on any airplane's first flight is not recommended particularly considering the years of work and cost involved in a Viggen as pretty as his.

All three pilots flew the airplane with mid reflex, as recommended in newsletter 12.

VARIVIGGEN PLACARDS In addition to labeling all switches and cockpit controls we recommend the following placards for VariViggen. Having an abbreviated checklist on the panel is real handy.

Radio call NXXX
Maneuver speed 108 kt (125 mph)
Gear actuation 75 kt (85 mph) one-g only
Max front seat pilot weight XXX lb
Min front seat pilot weight XXX lb
No aerobatics No spins
Solo Front Seat Only

Takeoff

Controls	Carb heat
Reflex	Mixture
Trim	Gear Handle
Instruments	Canopy
Harness	Liftoff 60 kt (70 mph)
Fuel	Climb 75 kt (85 mph)
Mags	

Landing

Mixture	Reflex
Carb heat	Approach 70 kt (80 mph)
Gear dn	Touchdown 50 kt (60 mph)

CAUTION: Trim changes with power--forward stick is required when power is reduced.

VARIVIGGEN PLANS CHANGES

Owners Manual page 37	Add "never exceed speed (red line) is 175 mph (152 kt) indicated."
SP Plans page 8	Block on inboard of aileron that is 1.3 inches high should be 1.5 inches high.

VARIEZE TECHNOLOGY TO BE APPLIED TO VARIVIGGEN Dave Burdette, who is building a VariViggen nearby, has caught the composite bug and asked us to design a glass and foam canard for his Viggen. So, after taking a

thorough look at the application, we've decided to also incorporate the high lift airfoil used on the EZ and increase the aspect ratio. This requires less area so the canard had to be tapered to fit the existing bulkheads and control system. Keeping the same elevator pivot at W.L. 18.0 resulted in a need for anhedral to keep the pivot geometry correct for the tapered elevator. The result is a wild looking canard, as you can see from the sketch. We expect to pick up a knot or two of speed and have the same low-speed performance. It should reduce the nose wheel lift-off speed at forward cg. Of course we can't sell plans for this until it can be flight tested. When? Well I'm done trying to guess how long it takes people to finish a VariViggen, but we'll keep you posted in the Canard Pusher. **SKETCHES OMITTED**

VARIEZE UPDATED BILL OF MATERIALS The basic "Section I" BOM (page 2-2) has undergone several revisions, the major one due to the aileron and backseat stick addition. The following is the current list:

EPOXY: RAEF fast cure epoxy 6 one-gallon kits
        RAES slow cure epoxy 7 one-gallon kits
        5 minute epoxy 1 two pound kit

FOAM: Rigid PVC
       16 lb/cubic ft., dark red color, 2 pcs. 60cmx56cmx5mm
       16 lb/cubic ft., dark red color, 2 pcs. 60cmx30cmx5mm
       6 lb/cubic ft., light red color, 2 pcs. 90cmx80cmx9mm
       6 lb/cubic ft., light red color, 2 pcs. 90cmx30cmx9mm
       6 lb/cubic ft., light red color, 1 pc. 15cmx27cmx25mm

       Large-cell expanded polystyrene with flame retardant
       2 lb/cubic ft. light blue color, 4 pcs. 9" x 18" x 67"
       2 lb/cubic ft. light blue color, 1 pc. 9" x 18" x 41"

       Rigid polyurethane slab
       2 lb/cubic ft., Green color, 5 pcs. 1" x 24" x 96"
       2 lb/cubic ft., Green color, 2 pcs. 2" x 24" x 96"
       2 lb/cubic ft., Green color, 1 pc. 2" x 24" x 48"

FIBERGLASS: RA5177UND unidirectional weave 70 yds. (38 in)
             RA5277BID bi-directional weave 119 yds. (38 in)

FILLER MATERIAL: Flocked cotton fiber, 1 lb.
                  Microspheres, PF grade inorganic Q-cell,
                  two one-gallon containers.

WOOD: Birch aircraft plywood, 5 ply. 24" x 36" x 1/4"
       Spruce or fir, 2 pcs. 1" x 0.7" (rectangular) 105 in.
       Spruce or fir, 1 pc. 1" x 0.7" (rectangular) 72 in.
       Spruce or fir, 2 pcs. 0.7" x 0.7" (triangular) 105 in.
       Spruce or fir, 1 pc. 0.7" x 0.7" (triangular) 72 in.

Aluminum sheet 2024 T3 Clad
.125 thick, 1 piece 110 sq. in.
.063 thick, 1 piece 54 sq. in.
???? thick, 2 pieces 12 in. X 12 in.
(.040 is acceptable substitute)
.020 thick, 1 piece 72 sq. in.
Aluminum 90 degree angle 2024-T3511
.125 X 1.0 X 1.5, extruded, 2 pieces, 30 in. long
.125 X .875 X .875, "   , 2   "   , 30 "   "
(.125 X 1 X 1 acceptable substitute)
.063 X 2 X 2, formed, 2 pieces, 12 in. long

Aluminum Tubing
1/4" OD X .032 wall   3003-0, 4 ft.
3/8 OD X .035 wall   3003-0, 8 ft.
5/16 OD X .065 wall, 2024-T3, 1.0 inch (one inch)
3/8 OD X .028 wall,   2024-T3 or 6061-T6, 2 inches

```
1/2 OD X .035 wall,   2024-T3, 3 pieces, 47 in. long
1/2 OD X .058 wall,   2024-T3 or 6061-T6, 8 inches
5/16 OD X .049 wall,  2024-T3 or 6061-T6, 4 inches
1 1/4 OD X .035 wall, 2024-T3 or 6061-T6, 1 piece 66 in.
                                          1 piece 84 in
3/4 OD X .058 wall,   2024-T3, 2 pieces 47 1/2 in. long
                 OR 6061T6    1 piece 23 in. long

Steel Tubing 4130-N or 1020
3/8 OD X .065 wall,   3.5 inch
5/8 OD X .049 wall,   23 inches
Steel Rod
3/8 OD common steel rod, alloy unimportant, 88 in.
several pieces ok.
Steel Sheet
.016 thick, type 301 or type 302 stainless, 1 piece 24" X 30"
.050 thick, 4130-N or 1020, 1 piece 9" X 2"

VARIEZE

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6',5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance. THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on

structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP AT GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	560 lb
Gross Weight	1050 lb
Range at Max Cruise	700 mi
Range at Econ Cruise	850 mi
Min Speed (full aft stick)	55 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6 square feet
Canard Span/Area	12.5'/13 square feet

SPECS & PERFORMANCE WITH 75-HP CONTINENTAL:

Take Off	1050 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	530 lb
Gross Weight	950 lb

THE FOLLOWING ARE RAF-AUTHORIZED DISTRIBUTORS OF VARIEZE MATERIALS AND COMPONENTS. CONTACT THE DISTRIBUTORS AT THE ADDRESSES SHOWN FOR THEIR CATALOGUES AND DESCRIPTION OF ITEMS.

AIRCRAFT SPRUCE & SPECIALTY CO.
201 W. Truslow Ave, Bx 424,
Fullerton, Ca. 92632
(714) 870-7551 All Raw Materials
Catalog costs $2.

PROVEN DESIGN Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS:
AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow, Box 424, Fullerton, Ca. 92632 (714) 870-7551.
VariViggen spruce kit, plywood kit, hardware, aluminum and fiberglass. Catalog cost $2.

KEN BROCK MANUFACTURING, 11852 Western Ave, Stanton, Ca. 90680 (714) 898-4366.
VariViggen prefabricated components: all machined parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton, Oh 45424.
VariViggen plexiglass canopy.

MONNETT EXPERIMENTAL AIRCRAFT, INC, 955 Grace St, Elgin, Il 60120 (312) 741-2223.
VariViggen molded fiberglass parts.
GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48706.
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509.
VariViggen welded nose and main landing gear, 1-1/4" sq. steel tube.

BILL CAMPBELL (VariViggen builder), Box 253, Phelan, Ca. 92371
VariViggen prefab brackets and fittings.

JESSE WRIGHT (VariViggen builder), 7221 S. Colorado Ct, Littleton, Co 80122.
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material

sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing; 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

VARIVIGGEN CONSTRUCTION MANUAL Part 1 of a photo-illustrated construction manual, written by Jim Cavis, S/N 31. Includes fuselage, canard, inboard wing, vertical stabs, control system, and landing gear, along with approximately 100 photos. Part 1 also includes helpful sketches on jigs and numerous building tips. The written information is similar to plans chapter 5, except expanded to about 30 pages. Price: $18.50 first class mail, $20.50 airmail overseas.

THE CANARD PUSHER NO. 14 OCT 77

NEWS OF THE VARIVIGGEN (very vig-in) and VARIEZE (very easy)

NEWSLETTER SUBSCRIPTION - $4.75/year
OVERSEAS AIRMAIL - $6.50/year
BACK ISSUES - $1.00 each

If you are building a VariViggen you must have newsletter 1 through 14.
If you are building a VariEze you must have newsletter 10 through 14.

BLDG. 13, MOJAVE AIRPORT
MOJAVE, CA. 93501
(805) 824-2645

SOME VERY SATISFYING events have occurred since the last newsletter. First flights of two VariViggens and about ten VariEzes have occurred during the last three months. The EAA convention at Oshkosh, Wi. had five VariEzes and one VariViggen attend, each being flown in from out-of-state, plus a static display of a nearly completed VariEze. RAF gave about 30 rides to builders during the show. Langhorn Bond, new FAA administrator got a ride in N4EZ and a demo of its stall resistance.

Last December the prototype VariViggen, N27VV, was promised to the EAA museum at Hales Corners, Wi. The day after the Oshkosh convention N27VV was flown to Hales Corners with Ray Hegy in his Chuparosa on our wing. We landed, taxied to the museum and left both airplanes to the care of the very able EAA museum personnel. It's a little heartbreaking to leave a perfectly good airplane in a museum. N27VV has given us some very satisfying flying experiences. She was flown to the annual Oshkosh flyin six years in a row. She took us on many a vacation trip loaded with baggage. She performed low level maneuvering demos at over 25 airshows, and was flown for a feature film, "Death Race 2000." It is quite fitting that N27VV be preserved at this facility in the years to come, as the future will recognize it as a forerunner of some significant developments in general aviation. Some of these developments are currently under construction at RAF and may enter the general aviation market within the next four years.

The events of Oshkosh 77 will not be covered here, since they are aptly described by Jack Cox in the October EAA magazine, "Sport Aviation." Be sure to read that issue; it has the first article to be published by a VariEze homebuilder/flyer.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Jim Cavis in N31VV before accident.

Mike Melvill during first flight.

Wally Warner in N455VV.

Wally's Viggen landing after first flight.

Warren Curd after first flight.

Peter Krauss's EZ: Note exhaust comes out top of cowl to meet the rigid German noise requirements. This is a straight pipe, no muffler, but ground noise is only 64 DB.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

An SP wing - the all-composite (glass & foam) outer panel that has been flown on N27VV for the last 2-1/2 years is now mounted as a picnic table in front of RAF. The sun & blowing sand environment of Mojave is excellent to determine, at an accelerated rate, the effects of ultra-violet radiation exposure on the composite structure. A portion of the wing is painted with Null-V.

Left to right - Johnny Murphy, George Gibbons, Burt, Dale Findley, & Lee Herron.

All eyes were on the flyby pattern as some EZ riders enjoy themselves.

Taxiing in, all speed boards out.

Dr. Lutz, getting his ride in N27VV

Lined up for engine start for a 4-ship formation demo on the "History of Flight" airshow.

N4EZ with load for Oshkosh trip. Crew weight 310 lb. Baggage included 3 suitcases plus misc items stowed in the spar and rear baggage area - 52 lb total.

EZ's at Oshkosh - left to right, C-85-powered N20VE flown from Cape Canaveral, FL by Johnny & son, Steve Murphy; Lyc O-235-powered N655EZ flown from Boston, MA by Ware Fuller & Dale Findley; O-200-powered N4EZ flown from Mojave by Burt & Carolyn Rutan; O-200-powered N101MW flown from St. Louis, MO by George Gibbons; and C-90-powered N1WZ flown from West Orange, NJ by Diane & Lee Herron.

Shot of wing & winglet at 12,500-ft over NM - Most of our Oshkosh trip was flown above 11,000 ft at 50% power about 175 mph true and 37 mpg.

Three EZ's take off to join the flyby pattern.

Discussing the plan for the next flyby.

Come on Lee - Flying an EZ is not that much fun!

Spirit of St. Louis framed by N1WX.

ONE MORE WORKSHOP
We are scheduling one more composite workmanship workshop. It will be an all day construction seminar and will include flight demos - all VariEze and VariViggen builders are welcome - bring your airplane or uncompleted part of your airplane. If you have a part in which you are unsure of its workmanship or acceptability, bring it so we can inspect it or use it as an educational sample for others. This is not a public open house; only builders are invited. It will be held at RAF, near the west end of the flight line at Mojave Airport, Mojave, Ca. (2-hr drive, north of Los Angeles on Highway 14), on Sunday, December 18, 1977.

FEATURE MOVIE TO USE VARIEZES
Ferde Grofe Films, in conjunction with the designers of the special effects and robots in STAR WARS, is planning a new film, CENTURION ONE. This is a Galactic Western where the setting is a hostile planet and instead of a horse the cowboys fly VariEzes. Studio sets will be used for many of the shots where the EZs will appear to hover, but real VariEzes will be used for flying photos. A lot of the flying filming will be done in the California Desert with as many as 10 VariEzes. Two EZs will be needed for some filming in some remote areas, including South America, Alaska, Africa and Southeast Asia.

Anyone interested in flying their own VariEze in this film? Contact Ferde Grofe Films, 18139 West Coastline Drive, Malibu, Ca. 90265

DID YOU KNOW?

That the long-sought Kremmer Prize for manpowered aircraft was recently won by a southern California group using a Canard Pusher-type aircraft.

That the new models of the Lear jet will use Whitcomb winglets.

That USAF will test winglets next year on a KC-135 tanker.

That NASA is considering new research to investigate the improved stall/spin characteristics offered by the loaded canard concept. A study of the Curtiss Ascender XP55, an aircraft plagued by bad stall characteristics, shows that if it had been modified to a loaded, high lift, high aspect-ratio canard configuration, it would have had excellent stall characteristics.

That Bill Lear got a set of VariEze plans about a year ago. That Bill Lear has just announced he plans to produce an all-composite airplane.

That RAF is about out of the first printing of the VariEze "Owners Manual" and it is being completely updated to show all revisions, current performance, fuel system, ailerons and landing brake. It will be available in November - ask for 2nd edition of "Owners Manual."

BUILDERS' CLUBS - Northeast VariEze/VariViggen builders Paul J. Dexter, 133 Hayden St., Orange, Mass. 01364, would like to form a regional association to help each other with building/flying activities.

Lee Herron, Box 357, West Orange, NJ 07052, is an EAA designee and is willing to help others with composite construction. Lee's VariEze appears elsewhere in this newsletter.

The Minnesota VariEze club is still the largest and most active. Contact George Wilson, 2924 108th NW, Coon Rapids, Mn 55433. RAF wants to thank the following members of the MVEC for their help running our booth at Oshkosh this year: Vic Berggren, Chet Ellingson, John Novy, Nat Puffer, Jim Tome, Chuck Weitzel, Ed Wieland, George Wilson, and R. Woodall.

Colorado VariEze squadron is now active. Contact squadron commander Lynn Miller, 7325 Tabor, Arvada, Co 80005. (303) 421-2261

Other clubs now active include Ohio (Bill Pritz, RR2, Belle Center, Oh 43310), southern Calif (Al Coha, 5173 Leo St, San Diego, Ca 92115), central Calif (RAF Squadron I, Ed Hamlin, 8377 Seeno, Roseville, Ca 95678).

If you are interested in forming a builder's club, contact RAF so we can mention it in a future issue of "Canard Pusher."

The following is the first flight report from a VariViggen homebuilder, Mike Melvill. We are of course pleased to find that his performance is exceeding that in the "Owners Manual!" Wally Warner's (Orland Park, Il 60462) VariViggen flew first flight only three days after Mike's. Mike's Viggen has the standard wing shape in glass and foam. Wally's has the SP wings. Both have 180-hp 0-360 Lycomings.

P.O. Box 561
Frankton, In.
46044
9-27-77

Dear Carolyn & Burt,

Well, we finally got there! At 11:30 AM 9-22-77 I took off from the Anderson Municipal Airport, and everything behaved as it should. I stayed up for about 45 minutes, did not retract the gear and made a perfect landing. I can not describe the feeling, it was absolutely fantastic. Thank you so much for a fabulous flying machine! Later the same day I climbed to 5,500 and retracted the gear and checked it out generally. As of today, I have 13.2 hours on it with no problems. At 7,500 in level flight, she trues out at 170 mph. at 2700 rpm. I have a 70x70 "Ted" prop, but for an 0-360 even that is not enough, as it will over rev at low altitude. At 3500 ft she will indicate 165 mph at 2700 rpm, but this is not full throttle. Initial climb solo is 1500 f/min. At 5000' solo she makes a steady 1000 ft/min. All systems operate perfectly, reflex, electric trim, and gear are really first class and I am very satisfied. My radios (TERRA 360 com & 200 NAV) are really outstanding, and the tower at Anderson says I have the best transmission of any radio in the area. I can not say enough about the airplane. She really is a hell of a fine craft. I love it.

empty wt. 1252 lbs

empty cg 132.78
main tank holds 24.7 gals
wings hold 6.5 each - 13 gals total

So far I have flown it at 125"cg, 124, 123, & 122. It handles well in all planes so far. Yesterday I loaded 170 lbs in the passenger seat and could hardly tell any difference. It takes 16 minutes to transfer 13 gals from the wings to the mains. Cyl head temp runs between 375 & 425, oil temp 165 degrees, ground handling is excellent, brakes are very good. Rotation with full throttle occurs with full aft stick at 70 mph indicated. Initial climb at 85 mph indicated for gear retraction, then trimmed down to 120 mph. for good cooling gives 1000 ft/min. R.O.C. Canard stalls at 60 mph indicated (airspeed may not be accurate at slow speed) will climb with canard stalling & unstalling, and is fully controllable. Side slips well.

Actually it flies just about like yours. I must say I really get a heck of a kick out of flying it. I will enclose some pictures. I painted it off-white with dark green trim.

Sally sends her best regards. Thank you again for making it possible.

Sincerely,
Mike N27MS
Ser#115

CP14, Page 3

VARIEZE CONTINENTAL ENGINE - installation in N4EZ has been flown about 53 hours since CP# 13. The installation continues to be trouble free. During the Oshkosh trip we found that it is rather susceptible to carb ice, similar to a Cessna 150. The carb iced up three times, each time carb heat was adequate to clear the ice. We found it advisable to cruise with heat on when moist air conditions, cruising at 50% power.

If you are losing more than 1/8 qt oil per hour out the breather, install an oil separator as shown below. This can be homemade by welding ends and tubes into a 4-inch length of 2-inch dia aluminum tube. Several commercial separators are also available. **SKETCH OMITTED**

LYCOMING 0-235 FOR VARIEZE
Good news - development of the stripped 0-235 is proceeding well and availability of section IIC is expected in late November. The 0-235 Lyc development is not being conducted at RAF. Air Sport, Inc., Minuteman Field, Boxborough Road, Stow, Mass. 01775, phone (617) 897-6021 is doing all installation development, all flight tests, and will be providing all homebuilder support concerning the Lycoming. RAF will sell the section IIC drawings at $21.50 ($23.50 for Air Mail over seas) starting in late November. Profits from sales of IIC will go to Air Sport. All homebuilders questions concerning IIC information should be directed to Air Sport.

The Air Sport EZ now has nearly 100-hours flying time and is very close to completion of required flight tests. Cooling, induction, controls, fuel system, exhaust, mounting and cowling have been essentially debugged. The Air Sport EZ is flying with a Jiran prototype Lycoming

cowling. The Lyc cowling is to be available from Jiran by late November (same price as Continental cowl).

Section IIC will include installation of all models of the Lycoming 0-235. The following stipulations must be adhered to: Slick mags must be used. Ring gear, alternator, starter and vacuum pump must be removed. The Lyc is mounted closer to the firewall than the Continental, thus, the balance of the airplane is the same as with an 0-200 with alternator.

Performance with the 0-235 is essentially the same as with the 0-200. Rate of climb will increase about 13% and cruise should be four to five mph more.

VW ENGINES FOR VARIEZE

We still do not have any encouragement to report as yet, except that a serious development program is still planned by Revmaster. Results of their tests will be published here when available. Looking at other programs though does not provide encouragement. It seems that reliable engine experience is the exception rather than the rule. Fred Keller again flew a VW-powered aircraft from Alaska to Oshkosh this year, but even after several years of development, the prototype KR2 and Mini Imp were trailered in.

The two Pazmany PL4A's at Oshkosh this year were powered by Continentals, even though the design and prototype were intended for the VW. Two other new VW-powered aircraft were at Oshkosh. One trailered in, another had an engine failure in route. The Sonnerai's appear to be having adequate reliability using VW's up to 1700cc, but above that (for adequate power for a VariEze) even they admit that reliability is in question.

TAKEOFF PERFORMANCE - Some EZ fliers who found takeoff distances were too long have found they could obtain the "Owners Manual" distances after assuring they met the following:

1. Brakes should not drag - align the nose wheel once on the runway before the takeoff roll so you don't have to ride a brake.
2. Tire pressure should be at least 55 psi; use 70 psi on the 4-ply tires.
3. Lift off at 60 kt (69 mph) at 900-lb gross weight and 66 kt (76 mph) at 1050-gross weight. Raise the nose early but only slightly; i.e. don't raise it high until the above speeds.
4. Be sure you are getting the correct static rpm. Minimum is 2200 for the 0-200, 2100 for A75 or C85, and 1900 for the A65.
5. The "Owners Manual" data are for the Ted's prop. While the Cassady prop is more efficient at cruise, it extends takeoff about 20%.

VARIEZE WEIGHT - A lot of the builders are losing sight of the fact that the airplane was designed for the A75 engine which weighs 170 lbs and without additional equipment. It is stretching things to install the 0-200 less electrical system (195-lb engine weight). It is really stretching things, compromising useful load and making the airplane tail heavy if you install the 0-200 with alternator or the stripped Lyc 0-235 (210 to 215-lb engine weight). You will probably be happier with

overall performance and utility of a 75 horsepower, 540-lb empty airplane than with a 100 or 108 horsepower, 650-lb empty airplane.

Some have commented that, "Oh, I only weigh 160 lb," or, "I plan to fly solo all the time, so I don't mind an extra 50-lb empty weight." This is foolish - the VariEze should always be flown as light as possible, not always be flown at gross weight. I put in enough fuel for the mission required. I fill up N4EZ only when I need the range. If you only weigh 160 lb, are flying solo, and have a light airplane, then you can enjoy some real benefits - spectacular climb; lower approach speed; shorter takeoff and landing; easier on structure, landing gear and brakes; easier to ground handle; much more fun to fly, etc.

Do not install any extras until you know what your final weight is going to be and if you can accept it. The cause for many of the overweight planes is excessive fillers, primers, and paint in the finishing process. If you can, weigh your plane before and after finishing, and let us know the data. We know of some finishes as light as 12 lb., others as heavy as 85 lb!

Bud Bryan's 0-200-powered EZ is now 570-lb empty after removal of alternator; his is the lightest 100-hp EZ I know of - a good goal to shoot for. You should consider an empty weight over 620 as totally unacceptable.

We have had several questions (particularly from those who have ruined their useful load with a heavy empty weight) about what happens if you try to fly over gross. This is not something to be taken lightly, since the number "1050-lb" is literally used over 1,000 times in the structural design, performance calculations, structural dynamics, etc. I have operated N4EZ over gross on about 20 flights, including our trip this year to Oshkosh in which we had full fuel on several flights and 52-lb baggage (see photo). This was a useful load of 529-lb and

---

Based on our operational data and a re-look at the structural considerations we can approve operation up to 1110 lb, but only under the following limitations:

1. At least 90-hp engine
2. Taxi and takeoff only on smooth, hard surface. Use 65-psi tire pressure on mains; 75 psi if 4-ply tires are used.
3. Maximum weight for landing limited to 1050 lb.
4. Maneuvers limited to normal category +4g, -lg. No intentional abrupt maneuvers.
5. Add 300 feet to gross weight takeoff distance, liftoff at 70 knots (80 mph), climb at 85 knots (98 mph).
6. Pilot proficiency - at least 50 landings in VariEze before attempting overgross operation.
7. High gross weight should not be considered for routine operation, since the chances of surviving an off-airport forced landing diminish rapidly as weight is increased.

The following list is all the instrumentation in N4EZ. This allows me to fly anywhere I want to go, excludes me only from the handful of large airports at the hub of the TCA's and provides adequate references

to penetrate a cloud deck if in an emergency and caught on top. Any equipment in addition to this list should be avoided, as it does not increase the utility at all, since night or IFR is not recommended.

airspeed	EGT
altitude	CHT
rate-of-climb	RPM
compass (wet)	oil p.
electric turn/bank (stand by)	oil t.
Escort 110 nav/com	

FRIGHT TESTING We recently observed someone taking his airplane to red-line speed for the first time at low altitude. Opening any airplanes envelope, be it a homebuilt or the 10,000th Cessna 150, is a risky flight test that should be done carefully. The first time you do stalls or open up the high speed area, do it at high altitude and wearing a parachute.

VARIEZE PITCH SENSITIVITY - I have flown seven VariEzes and thus have been able to compare variances in flying qualities. In general most have been more sensitive or more difficult to fly in pitch than N4EZ. We have investigated why the average EZ does not feel as "solid" in pitch as N4EZ and have identified the following causes- be sure to check all of them on your airplane.

(1) Control system friction - the system must be smooth and friction-free. If yours is binding or rubbing, fix it before you fly.
(2) Elevator dimensions - check these dimensions on your elevator, measured with the bottom of the elevator level. The airplane will be more sensitive if A is too large or if B is too small. **SKETCH OMITTED**
(3) Aftcg - Those with the big engines with alternators, or those with light pilots are finding that their airplanes are tail heavy. A tail heavy airplane needs to be ballasted with nose weight to obtain a proper cg. To avoid adding a lot of dead weight, it is tempting to fly the airplane near the aft cg limit. This is ok once the pilot is proficient but aft cg makes an airplane more sensitive and more difficult to fly. Thus, we recommend that you initially fly at mid to forward cg, i.e. in the forward part of the first flight box.
(4) Trim authority - The airplane is easier to fly when in trim. To be sure you have enough trim for low and high speeds, check the following and adjust trim springs accordingly: With trim set at full aft (cable wound up to the nicopress sleeve) and stick held neutral, the force at the stick grip should be about three to four-lb aft. With trim set at full forward (cable unwound) and stick held neutral, the force at the stick grip should be about one to two-lb forward.

Those of you who do have the heavier engines and alternators are finding that the nose weight needed to get the cg forward is cutting into your useful load, already reduced with the heavy engine. If this were a conventional airplane there wouldn't be much you could do, short of moving the engine or wing. But, since the VariEze has two widely separated, lifting wings, the allowable cg range can be shifted by shortening or lengthening the canard. Thus a "tailheavy" airplane can

be made to fly "nose-heavy" merely by sawing off canard span, making no change to actual cg! This can be done only up to a point, where directional stability is lost as cg is moved aft. We have tested the flying qualities and confirmed that the canard/elevator is free from flutter at two canard spans - 150" as shown in the plans and 142" which is obtained by sawing 4" off each tip. If 4" is sawed off each canard tip (142" span) you can move the allowable cg range aft 1.2 inches. This is equal to adding 15-lb weight in the nose at F.S. 5.

Let's look at a couple of examples to see what this canard trim can do for you. Assume you weigh 170 lb and you are using an 0-200 with alternator and a small battery. When you do your weight and balance you find you will need 30-lb ballast in the nose to get to the nose heavy condition (preferred for low pitch sensitivity) for first flight. Then later you can remove 1/2 the ballast, but will have to carry 15 lb of lead in the nose for the life of the airplane. If you trim the canard you will find that you only need 15-lb ballast to get to the forward cg you need for first flight. Then, when you are comfortable with the stick forces you can remove all ballast and have the best useful load and a mid to aft cg. Thus, trimming the canard has increased your useful load by 15 lb!

As another example, let's assume you have built an EZ with the engine it was designed for, the A75 Continental. When you do your weight and balance you determine the allowable pilot-weight range is 125 lb to 240 lb. You, yourself, only weigh 130 lb. You note then, that you will always be flying a sensitive airplane (near aft cg limit) unless you carry ballast. You also note that you don't have any friends that want to fly your airplane that weigh over 210 lb. Thus, you decide to trim your canard. With the allowable cg range back 1.2 inches you re-calculate your allowable pilot range as 95 lb to 210 lb. Now, you can fly a "mid" cg range without adding ballast, and your 90-lb wife can fly with less ballast.

In summary, the canard trim to 142-inch span lowers the allowable pilot weights about 30 lb. If the airplane were originally designed for the 0-200 with alternator the canard would have been about 142 inch span. Do not trim the canard to less than 142 inches, in hopes of using further aft cg (aft of 102.2) to balance a heavy Lycoming and a light pilot Directional stability may degrade aft of 102.2 and the canard has not been tested for flutter at less span.

The best time to decide if you want to trim

---

your canard is when you have done your final weight and balance and have calculated your allowable pilot weight range and compared it to your weight. However, if you know you are going to use an 0-200 or Lycoming 0-235 and your weight is less than 180 lb, go ahead and trim it now, before your paint job. Same goes for even the A75 engine if your weight is less than 150 lb.

The canard can be trimmed easily without much disruption of the paint job. Refer to the sketch. Using a hacksaw or coping saw, saw off 4 inches from the tip of each elevator. Now saw a 4-inch section from

the canard as shown so the tip can be glued back on (wet micro) and no recontouring of the tip will be needed. **SKETCHES OMITTED**

VARIEZE LANDING GEAR - We are asking all of you to make a change to the main gear mounting tabs. This change is not based on any problem with N4EZ nor any drop test result. N4EZ now has about 500 landings, some of them at gross weight and a few of them quite hard. There has been no deterioration of the gear or attachments, so it is a bit confusing to us to learn that 3 or 4 of the homebuilt Ezs now flying have had failures. One was a complete failure of the tab that allowed Cy Mehling's gear to rotate forward, dropping his airplane on its belly while taxiing. Others were discovered before they completely failed. In one case the bolt or spacer had worked in the tab enough to allow the inside and outside pad layups (page 18-2) to move relative to each other, thus partially peeling the tabs from the strut and making the strut loose. Because these failures are apparently not isolated cases but are affecting a large percentage of the builders we recommend that you update your gear to the configuration shown below before you taxi or takeoff.

The modification does two things. First it adds additional material to the tabs and second, it allows the inside and outside pads to bond directly to each other, preventing the relative motion allowed by the previous foam tab. Here's the method for original construction: make the tabs as shown on page 18-1 from 1/4" plywood, not foam. Instead of the two 3/16" spacers, make the spacers in-between the tabs 1/4" thick and the outside spacers 1/8" thick, otherwise follow step 2 exactly. Modify step 3 as follows: make only the inside layup, using 22 plies BID. Clamp lightly (too much pressure will drive out too much resin) and allow to cure. Using the tab as a guide, drill through the inside pad and trim the edges even with the tab. Now completely remove the tab and sand the faces of the inside layup dull. Do not be concerned if you have to remove a little of the gear strut to fair into the trimmed tab. Apply the outside pad layup using 25 plies all around and an additional 8 plies on each side that just lap over the leading and trailing edges. Clamp lightly and cure. Continue, following step 4. This will now result in a solid glass tab in the 5/8" gap between the aluminum extrusions. **SKETCHES OMITTED**

Do not make the layup wider than 2 inches. A wide layup will stiffen the gear locally and can result in the strut peeling away due to bending loads.

If your gear is already mounted, use the following procedure: saw off the bottom cover from the rear seat, back about 12". Remove the gear. Peel off the 15-ply outside layup pad (chisel and hammer.) Completely remove the foam tab. Layup about 6 plus on the face of the inside pad, butting them against the gear leg. Trim the strut as required for a smooth corner without a joggle. Layup the 25 and 8-ply outside layup as shown above.

Be sure to check that you have the correct 0.6-inch edge distance all around the tab. Cy Mehling's tabs were only 0.33" at the point of failure. **SKETCHES OMITTED**

Since I have been alerted to the failures in this area I have been keeping a close look at the tabs on N4EZ. The forward tabs are

difficult to see, so I made a 3-inch diameter hole in the rear seat bulkhead immediately in front of each tab, to allow inspection. I recommend that you make these holes in your airplane. They do not show, since they are covered by the back seat cushion. Use a pin router or hole saw.

CP14, Page 6

While on the subject of gear strength, a reminder is in order to check that the nose gear strut is installed properly. If this is done wrong its strength is as low as 1/10 and will barely support the airplane's weight for taxi! **SKETCHES OMITTED**

Several builders have had various problems with the Rosenhan wheels/brakes. If they are not kept in adjustment they can allow the piston to move too far out and result in O-ring failure. They must be adjusted as follows: turn the adjustment nut until the wheel will not rotate by hand. Back off 1/4 turn only. Check adjustment often. Use only the red MIL H 5606B aircraft fluid. Aircraft Spruce has it by the quart. I have been discussing the homebuilders' experiences with Fred Rosenhan, manufacturer of the wheels. He informs me that he now has a direct-puck actuation brake pad (like Cleveland) in the prototype stage. If it is successful it should increase the effectiveness of braking and eliminate need for adjustment. It is being designed to retrofit on the current Rosenhan wheels. We will keep you posted on the progress of this item.

When you drill the holes to join NG10 and the NG11 block, NG10 must be fully in the lock notch in the instrument panel. If this hole is drilled with NG10 to the left in the slot, the NG11 will not be fully engaged in NG13 with NG10 locked. This can result in NG10 popping out of its lock and the nose gear retracting. This happened 3 times to Dale Findlay on his trip to Oshkosh. Our experience has been that as long as NG11 is snubbed firmly into NG13 on both sides with NG10 in the lock, the nose gear has a very positive down lock. Be sure that the knob has the full one inch of snub (page 17-10) The weakest link in the nose gear is the NG10 pushrod which will buckle between NG11 and NG9 if an overload occurs.

Peter Krauss modified the NG10 lock with a system that is more complex but eliminates the need for NG10 to move sideways and provides a more positive lock. The mod involves making the slot in the instrument panel a straight line. A bracket is added that snaps over NG10 when snubbed down. The pilot must push the bracket out of the way to retract or extend the gear. **SKETCHES OMITTED**

VARIEZE FUEL SYSTEM

It has been determined that, due to a vendor error, some of the fuel cap O-rings in the Brock caps are of the wrong material. They will swell when wet with fuel and make the cap difficult to install. To check yours, soak your cap in fuel. If the O-ring swells enough so it doesn't fit the ring properly, return your O-rings to Brock for replacement.

It is possible to place the main fuel tank drain fittings (CP #10 pg. 6) in the tank such that they do not drain the low point during nose

down parking. This can allow water to remain after draining. Refer to the sketch and build a ledge in front of the fitting (if necessary) such that the drain is at the lowest point. The ledge can be urethane foam with one wet ply of BID. **SKETCHES OMITTED**

The fuel shut-off valve, when received has high friction. This is reduced when wet with fuel. Slosh your valve with fuel before installation to remove any grease and to verify that it does not bind excessively. The torque tube, installed as per newsletter 11 has a gentle curve from front to rear and is supported at the rear stick area. Some builders have found that one of the following methods improved torque tube operation and installation. **SKETCHES OMITTED**

When installing the fuel system be sure all components are placed exactly as shown on the drawings. Be sure the tee sits flat on the floor and the note on the bottom of CP 11, page 6 is followed. Do not vent the fuselage tank to the same vent as the wings. With separate vents you have redundancy in case the fuel vent gets clogged.

CP 13 alluded to the possibility that the Bendix carb will not work (pg 1). Johnny Murphy now reports his problem was a totally blocked vent, and once cleared, the fuel system operation is excellent with the Bendix carb. Johnny discovered the blocked vent only after a forced landing in which he had to glide 10 miles to an airport.

Do not modify the fuel valve's design feature that causes it to interfere with the pilot's wrist when the fuselage tank is selected. Already one VariEze has had a forced landing when the pilot ran the fuselage tank empty during touch and go's. This would not have happened had he done at least one of the following correct things: build the valve handle to plans, read the checklist, select the other tank when engine fails.

Remember, the fuselage tank is only required to extend your range by allowing full use of the two gallons of unusable wing fuel (unusable in extended descents). Unless you are stretching your range over 700 miles you never need to select the fuselage tank. You will find that you rarely use fuselage fuel, but it is extremely useful to be able to completely use all wing fuel when needed due to headwinds or weather. The fuselage tank also provides redundancy. If the cause of an engine failure is unknown, immediately select your other fuel supply.

CP14, Page 7

VARIEZE EXHAUST SYSTEM - As you know from CP 13, the four-post exhaust system had to be shortened to avoid vibration failures. CP 13 instructed you to shorten your system but did not have a drawing showing all details. The drawing below shows what the system looks like after shortening. Note that it must fit rather tight on the intake manifold to allow adequate cowling clearance. If you have an original-length system from mild steel, saw out a portion of the horizontal length and take it to a welder to get it welded - most auto muffler shops can do an adequate weld on mild steel tube.

The quiet muffler system mentioned in CP 13 has been flown on N4EZ. It is very quiet, weighs about 8 lb, but presently robs too much engine

power. The manufacturer is now modifying it to lessen the power loss. Installation of the two-can muffler system requires "bumps" to be added to the lower cowl (see sketch). It is similar to a Cessna 150 in external configuration, but has far superior sound deadening qualities. We hope to have its development completed in time for it to be available when CP 15 is published. **SKETCHES OMITTED**

VARIEZE PLANS CHANGES - Be sure to copy these into plans.

Section I, A3	Add the following dimension to all four landing gear extrusion drawings: **SKETCH OMITTED**
Aileron Addendum Page 5	The ZigZag hotwire template for template Y and B has the ZigZag misplaced too far forward. Move the ABCDEFGHIJK ZigZag lines back 0.2" toward the trailing edge.
Section IIA, pg. 13	Drill a 1/4" hole in the low point of the air inlet hose to drain fuel for a flooded start. (low point with gear retracted).
Section pg. 18-2	Modify main gear tabs as shown in this newsletter.
Owners Manual page 28	Replace cg chart with those on page 6 of this newsletter.
Section I page 24-4	The 0.3" dimension should be 0.75. This results in the lower winglet being canted outward about 30 degrees from vertical to lower dihedral effect and reduce wing rock at low speeds.

NOTE: Stall characteristics have been found to vary from airplane to airplane. Most Ezes and Viggens are not susceptible to departure and can be flown trimmed at full aft stick. Some do exhibit more wing rock than others. Peter Krauss reports that his Eze cannot be flown at full aft stick; that at about 60 mph one wing drops abruptly. This is probably due to incorrect wing twist, as Peter's airplane has required a relatively large trim tab on the wing. Be sure to determine your airplane's stall characteristics at altitude and with a parachute.

VARIEZE BUILDING HINTS - Thanks again to those donating their ideas for this column. Be sure to note the building hints from all letters into your plans so you won't forget them when you reach a particular point during construction. When submitting a building hint please include a self-addressed stamped envelope so you can receive our comments.

Ray Mucha - "When joining canard and wing cores first put the templates together and drill the nail holes all in the same place. Then later when the cores are joined, a wooden Q-tip stick or round toothpick in a few of the nail holes will hold the cores in alignment."

Bill Rice - Low cost syringes in 3cc, 12cc, 35cc, and 60cc used by large-animal vets, can be used and reused to measure resin and hardener. Be sure you check the ratio obtained on your epoxy balance to confirm you are getting an accurate 1-to-5 by weight ratio."

Jim Smith - "Rather than using only the top template to check canard incidence, a double one (as shown) clamps completely over the canard to give a more accurate incidence check that is less affected by local bumps." (See photo.) **PHOTO OMITTED**

Phil Supan - "Use a plastic garbage-can liner to keep epoxy off clothes. Cut three holes, one for your neck and two for arms."

Problem - Dacron peel-ply material wrinkles and is difficult to stipple into place. Solution - use Dacron surface tapes, available in rolls in the correct 2.7-oz weight (Aircraft Spruce catalog pg 99). Apply the tape in individual strips over large areas. You will need about three rolls of 1" tape and 2 rolls of 4" tape.

Dale Findlay - Dale devised a clever way to lock the canopy from the outside by installing a removable link between the canopy handle and the lever for the speed brake. When the speed brake is closed from the outside, the canopy is secured. To open the canopy he pries the speed brake open, which opens the canopy handle! The link is a piece of .063 2024 with two holes about 5.8" apart.

Vic and Mary Sullivan - "Any type cake decorator's cone can be used to apply dry micro. After hot wiring the aileron piece from the wing, nail it back into place so you have the full straight trailing edge available to accurately jig the wing. Remove it before skinning wing."

Dick Cobean - "Updating plans is easy if you Xerox the newsletters then cut and paste the hints and changes into your plans."

Some builders are still having problems drilling and tapping the steel inserts in the canard for the lift tabs. We recommend only the method using the predrilled 1/8" aluminum insert with nutplates installed (see newsletter #10, pg. 3).

Robert Purdy - "When drilling the NG13 holes in NG30 plates, clamp the NG30's together, clamp the NG13 on and use it as a drill guide. (page 17-5)

Cy Mehling - "Failures that occurred with the 5 volt regulator in the roll trim circuit were solved after installing a 10 watt, 50 ohm resistor in the lead to 12 volts." This is the only case I know of here - has anyone else had to replace the regulator?

If you have purchased a Jiran mounted canopy be sure to check its width before mounting the reinforcements and laying up the inside skin. It may have to be bowed inward somewhat to have adequate room for mounting the 3 brackets on the left side.

When the Jiran fuel tanks are trimmed to fit the fuselage side and wing rib they may end up about 0.8" aft on the fuselage as is shown on the plans. This is ok.

If you want to reverse the canard tab bolts to allow forward removal (CP #13, pg 5), install the nutplates on the back of F22 as follows: rivet the nutplates to a 1.5-inch dia. piece of .125-inch thick aluminum. Bond the alum washer to F22 and overlay with one-ply BID to secure it.

Pieces of BID cut at 45 degrees are easily distorted if picked up incorrectly and will not fit the part without a lot of cloth movement in place. To avoid this, roll the piece up while it's still on the flat cutting table, carry it carefully to avoid stretching, then roll it onto the part.

One builder reports his fuel gauge is not readable in other than ideal light. The key to good gauge contrast is to avoid any trace of foam or micro in the gauge area. Lay a strip of gray duct tape or plastic electrical tape in the gauge area before glassing the inside of the fuselage. This saves the work of sanding away all traces of foam. Remove tape before glassing outside. Be sure no micro gets on gauge. Sand both sides smooth and coat with epoxy.

You can generally tell the quality of a man's workmanship just by looking at his shop. Clean up and sweep after every step. Keep your tools organized and clean. Dirt in or under a layup will increase weight and decrease strength. A clean shop will reflect on your airplane, and will make construction more pleasant.

A flour sifter is excellent for getting any lumps out of micro. Keep micro bag closed to avoid moisture.

A key to a good glass layup is preparation. Copy the check list below and post in your shop:

BEFORE ANY GLASS LAYUP

1. Tools cleaned & available
   squeegee cups & sticks
   brush scissors
   roller ply 9 or gloves
2. Workbench clean
3. Glass cut & rolled
4. Surface to be glassed -
   correct shape & smooth contour
   sanded dull
   dust blown or vacuumed off
5. Temperature of room and epoxy 70 to 80 degrees F

VARIEZE ERRORS - HOW TO FIX

Now that the plans are essentially debugged by CP #10 through #13, the most common call or letter we get from builders starts with, "I goofed, how can I fix it?" The following are accepted practice to repair common errors. Of course, it's best to be careful and avoid the error in the first place. Remember, most errors can be avoided by reviewing your newsletters.

ERROR: Depression in skin or spar cap in span wise direction on wing, winglet, or canard.

REPAIR: Sand surface dull. Layup UND plies cut as shown to fill depression, fiber orientation spanwise. Add one ply BID at 45 degrees lapping two inches on each side of depression. This repair is allowable for depressions up to 1/10 inch deep. **SKETCH OMITTED**

ERROR: Bump in skin or spar cap in wing, winglet, or canard. REPAIR: Using a hard block, sand bump level. Determine number of plies in area of bump. Sand completely dull the area around bump to a radius in inches equal to number of plies at bump. Layup the same plies as effected area, being sure to observe fiber orientation. Add one ply BID at 45 degrees as shown. **SKETCHES OMITTED**

ERROR: Inadvertently sanded through plies during finishing process.
REPAIR: Determine number of plies damaged. Repair as shown in "bump" repair above.

ERROR: Due to incomplete wetting of layup I have several pin holes in my wing fuel tank so it will not meet leak check.
REPAIR: Pull a mild vacuum (1500 ft) on the tank. Hold the vacuum for 1/2 hour as you brush, stipple, or rub epoxy over the area with pin holes. Then vent tank to equalize pressure. Paint a coat of epoxy over effected area. Be sure tank is vented during cure.

ERROR: Sparkplugs strike top cowling due to cowl being installed too low.
REPAIR: Cut holes in cowl over sparkplugs and build bumps (CP #8, pg 7).

ERROR: Drilled out threads on one of the wing attach bolts.
REPAIR: Install a nut on the bottom - dig out and replace foam from the root end.

ERROR: Air bubble caused by attempting to glass around corner without radius.
REPAIR: If height of void is less than 1/10 inch, drill two small holes and force epoxy into void. If bubble is large, sand away and follow repair for "bump" above.

ERROR: Foam cores jigged in wrong position so that wing or canard will have joggle when glassed.
REPAIR: Cut core loose and bond (wet micro) in correct position before continuing.

ERROR: Glassed surface feels "tacky" after one day cure - This is generally due to improper measuring or mixing of epoxy (too much hardener).
REPAIR: Raise temperature to 80 to 90 degrees for several days. If still tacky and surface will not make a white mark when scratched with a sharp knife, the layup will have to be stripped (peeled) off and redone. Before continuing, do a test mix in a cup and check its surface for a good white scratch mark after cure. Check resin or hardener for settling (CP #12, pg 4).

ERROR: Due to a poor or heavy layup, elevator or aileron will not balance to specification.
REPAIR: Start over; sloppy workmanship cannot be patched on these parts.

ERROR: After wing was completed I noticed that shear webs were butted on sides, rather than top and bottom.
REPAIR: This is a very extensive repair but does save $ and time over the job of completely replacing wing. Cut skin as shown on wing bottom. Remove foam wedge. Sand entire shear web face dull and glass with 3-ply BID at 45 degrees. Put in new foam wedge with wet micro. Be sure wedge fits well to avoid exotherm. Patch skin as shown in "bump" repair above. **SKETCH OMITTED**

QUESTIONS/ANSWERS - Your questions can be answered directly if you include a self-addressed, stamped envelope.

Q - I know bare foam must be protected from sunlight and the epoxy must have an ultra-violet barrier to protect it from long term exposure, but is it okay to put my unpainted structure outside for a couple of days for rigging?
A - Short exposure is okay, but if it is for more than a few hours it should be covered (paper or cloth is ok).

Q - Is there any way to check the incidence of my winglets after the airplane is built?
A - The method shown below is an easy way to confirm that the left and right winglet incidences are equal. Measure "A" from the winglet leading edge at the wing top skin to a point on the aircraft centerline (prop hub or spinner tip). Measure "B" from centerline to the winglet trailing edge at bottom of rudder (rudder held neutral). Check that "A" minus "B" is the same for left and right winglets.

Q. I have built one wing with 90-deg fiber orientation on the BID rather than the 45-degrees shown on the plans. Is this ok?
A. No! Fiber orientation plays a very important role in the stiffness and strength of a composite structural component. Do not modify orientation, even on a bulkhead.

Q. I have bolted my Cleveland wheels and brakes to my axles but things don't fit right. What now?
A. Check two things - orientation of torque plate (CP 13 pg 6) and spacer rings. Two rings per axle must be used to not only space bearings but to provide dirt seals. Spacer rings are available at Aircraft Spruce and Brock.

Q. My cockpit vent on my Ez does not flow air below 100 mph. Can I fix this?
A. I have noticed this on other EZs I have flown. N4EZ's does flow down to 60 mph. I think the difference is due to a change in slope of the canopy frame. The change was made after N4EZ was built to improve forward visibility. I think your vent will work at lower speeds if you carve a smooth radius on the front and sides and raise the rear lip about 1/4 inch.

SHOPPING
We have found another source for the epoxy layup rollers. They can be mail ordered from IASCO, 5724 W 36th St, Minneapolis, Mn 55417. Ask for 1-1/2 texture roller - 99 cents each.

The diode for the Edmund solar panel (CP 13) can be two 1N4004 silicon rectifiers in parallel. We have not yet been able to get a thin solar panel produced, but we do have someone working on it. Energy Saving Systems, 8800 W Chester Pike, Upper Darby, Pa 19082, has a unit similar to Edmunds. If anyone knows of a source for a panel at a price less than $40 per watt, please let us know.

Jim Cavis reports that he is working on the second part of the Viggen construction manual and that repairs to N31VV are in progress.

WANTED: Completed VariEze, all considered. Barclay, 1109 E Broadway, Glendale, Ca 91205 (213) 241-4835.

FOR SALE: Partially-complete VariEze including C-85 engine. Cecil Muchmore, 7237 Via Amorita, Downey, CA 90241 (213) 927-5802.

FOR SALE: VariViggen project incl 0-320 Lycoming, almost all parts. Bill Lake, 1094 Madrone Way, Livermore, Ca 94550.

VARIEZE BILL OF MATERIALS
Most builders are finding that the kit has ample epoxy, enough glass if you use scraps wisely, but only about 1/2 the required amount of microspheres.

VARIEZE AND VARIVIGGEN RETENTION OF CANOPY
As we have mentioned several times before canopy retention is very important. An inflight canopy opening has resulted in the destruction of Tony Ebel's VariEze and a horrifying pattern flight by Peter Krauss. Peter took off without the canopy locked. It opened wide open at 100 mph during the initial climb. He grabbed it, pulled it closed on his fingers and held it while he returned for a good landing. Tony had a canopy latch that was adjusted so loose that it allowed the canopy to rise and fall noticeably during flight. Tony was flying at 6000-ft altitude and 185 mph true (165 indicated) when the canopy opened. He doesn't remember if he had bumped the latch. When it opened the airplane immediately departed from controlled flight, yawed, pitched down past vertical, did a 1/4 turn spin, then pitched up. Tony grabbed the canopy, it was pulled from his hand and the airplane repeated the above maneuvers. This happened about six times until he finally got the canopy closed with fingers outside (Tony did not have the knob installed on the inside). Once recovered to level flight (only 800-ft altitude) he noticed that his prop was stopped and thus he had to make a forced landing.* Due to a combination of almost passing out and fear of the canopy opening, he did not flare. He shoved the stick forward near impact. His own words follow:
"When the canopy opened, it was as if someone threw a hand grenade.** It really startled me. I knew I was in trouble. The plane shuddered and shook. Then started a left turn. It slowed down very fast.

After the first few wild gyrations, spins to the left, recovering straight down, etc., I got it to stall, nose high, and tried to close the canopy. As it fell, the canopy pulled open. This went on for the 5000 ft I fell. I wish I had tried a steep right side slip, or a full power stall, while trying to close the canopy. I was in (a) tense situation, real busy, jump or close it. I did not register any other event. As soon as the canopy came shut, and I noticed that the engine was dead, I had a thought that the sky was getting overcast. I had trouble thinking, finding a field and getting in position. I put the gear down. Then just as I landed, I thought..why did the sun go down? So I shoved forward on the stick, but the bean field was real dark, I heard the nose wheel breaking. Nothing more till after the wreck. So I was out, before I hit anything. Probably lack of oxygen, as maybe I was not breathing much on the way down.... I knew the fence was just ahead. I had tried a 90 degrees turn at about 70 ft., had to level it just before I landed, got 45 degrees of the turn.

Next day I walked the field. It was smooth and solid. So the gear probably would have stayed on, but I would have hit the fence.

I know now..don't try to knock the gear off by pushing on the stick. If I would have been really alert and not passing out, I could have landed in a circle and gotten away from the fence.

Spread the news that I have a good canard, good canopy frame and a repairable left wing for sale, damaged fin and tip, good fitting." Tony's airplane dug a large hole, cartwheeled once, tore off the right wing and ended up inverted. Tony dug himself out and found that his injuries were minor - cuts and bruises. The airplane was extensively damaged. Since this was the first major overload failure condition on an Eze structure, I was quite interested in inspecting the modes of failure. I flew over the next day and observed the following: wing failure occurred in the spar caps, 3 to 6 inches from the wing fitting - there was no damage in the fittings, winglets failed either in the wing or at the winglet 1/2 span. The joint did not fail. The canard, itself, was not damaged. All seat belt fittings were intact. The canopy plexiglass was broken in front but the canopy frame was not damaged. The forward fuselage back to instrument panel was totally destroyed. The rear seat area, fuel tanks, c/s spar, fuselage tank, etc., were undamaged. The engine, mount, firewall and everything in engine area were intact and not damaged. Nosegear strut and all its fittings were undamaged. The maingear tabs failed. The gear strut failed at 1/2 span.

* While the prop will windmill down to 60 kt, once stopped you must go above 120 kt to restart. Tony's engine failed due to negative "g" at a speed below 60 kt during gyrations.

** At that high speed it is surprising that the canopy was not torn off. The gyrations at that speed (above maneuvering speed) also should have resulted in airframe failure, but none occurred.

I am confident that inadvertent canopy opening cannot occur if the canopy is built and adjusted properly and locked before takeoff. The handle should be rigged so it must be forced hard forward to engage the latch. The latch and handle should be rigged for preload toward each other. Thus it is impossible to open it by bumping the handle. It

should take two hands to open. Be sure the latches engage fully in the positions shown on the plans. Do install the warning horn that sounds if takeoff is attempted without canopy fully locked. Do use your checklist. Do not omit the canopy inside knob.

CP14, Page 11

VARIVIGGEN PLANS CHANGES

Pg 41	Shorten FP3 0.8-inch to move master cylinder closer to pedal, to increase brake effectiveness. Pedal must be vertical or canted aft at the top for best brake effectiveness.
Cowl installation instructions	Baffling must fit tight all around with no large leaks, to prevent overheating.

NOTES FROM THE DISTRIBUTORS
Jesse Wright now has a VariViggen tail rib kit. Contact him for details.

Note the new address and phone number for Cowley, Inc. on the enclosed flyer. All plexiglass work is now done at Mojave. Send SASE for info to them. Remember that if you drive in or fly in to get a canopy it comes in a 96x26x14-inch box, which will not fit in a small sedan.

Jiran - all items except wheel pants will undergo about a 10% price increase, due materials & labor inflation, on 1 Jan 78. Jiran needs input from you to determine volume of Lycoming cowlings. They will be in production soon. Backlog is still about two months for gear; less for other items. Send SASE for current delivery status. Send 35 cents postage for complete brochure.

Brock - current backlog is still six to eight weeks, but panic needs can be filled in less time. Brock's $1 catalog shows photos of all available parts; many parts are available that are shown as homebuilt-only in the plans. See his catalog for complete list. Brock now stocks the pin router mentioned several times in the plans, as well as piloted countersinks.

Aircraft Spruce & Wicks can still supply a complete kit for pickup if given about two days notice.

Aircraft Spruce has recently added a few hard-to-find items not listed in catalog:

1. Instrument quick-handy template for layout of instrument holes - all sizes $6.75
2. 3 in 1 engine gauges - oil temp & pressure + fuel pressure.
   15' capillary for VariViggen $65.
3. Epoxy wood sealer for VariViggen inside sealing $11.75 per qt.

GLASS AND FOAM STANDARD WING FOR VARIVIGGENS

We have worked with several VariViggen builders on an individual basis concerning how to build a standard-shaped (like the metal wing) wing panel out of glass and foam (like the SP plans). Now that a glass and foam standard wing is flying, we are passing the information on to you here. For all details of construction not shown here refer to the SP plans. Also, follow newsletter hints for VariEze concerning glass work.

Use the lofts on page 8 and 9 of the plans for templates at B.L.48., 79.5, and 114. The stub spar is 31.5" long and is shaped to fit the cores less the thickness required for glass spar caps (.012 per ply for 5277; .009 for 5177).

Follow SP plans for spar cap dimensions and all fittings. Follow the sketch below for aileron size and skin glass configuration. The best epoxy is RAES (1 gal required) for foam bonding and heavy caps and RAEF (3 gal required) for skinning. Refer to your buddy's set of VariEze plans for additional hints on the glass work. 5277 is called BID; 5177 is called UND. **SKETCH OMITTED**

VARIEZE

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6',5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its

stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance. THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800

drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP AT GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	560 lb
Gross Weight	1050 lb
Range at Max Cruise	700 mi
Range at Econ Cruise	850 mi
Min Speed (full aft stick)	55 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6 square feet
Canard Span/Area	12.5'/13 square feet

SPECS & PERFORMANCE WITH 75-HP CONTINENTAL:

Take Off	1050 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	530 lb
Gross Weight	950 lb

THE FOLLOWING ARE RAF-AUTHORIZED DISTRIBUTORS OF VARIEZE MATERIALS AND COMPONENTS. CONTACT THE DISTRIBUTORS AT THE ADDRESSES SHOWN FOR THEIR CATALOGUES AND DESCRIPTION OF ITEMS.

AIRCRAFT SPRUCE & SPECIALTY CO.
201 W. Truslow Ave, Bx 424,
Fullerton, Ca. 92632
(714) 870-7551 All Raw Materials
Catalog costs $2.

PROVEN DESIGN Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43

kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS:
AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow,
Box 424, Fullerton, Ca. 92632 (714) 870-7551.
VariViggen spruce kit, plywood kit, hardware,
aluminum and fiberglass. Catalog cost $2.

KEN BROCK MANUFACTURING, 11852 Western Ave, Stanton,
Ca. 90680 (714) 898-4366.
VariViggen prefabricated components: all machined
parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton,
Oh 45424.
VariViggen plexiglass canopy.

MONNETT EXPERIMENTAL AIRCRAFT, INC, 955 Grace St,
Elgin, Il 60120 (312) 741-2223.
VariViggen molded fiberglass parts.
GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48706.
VariViggen 105/206 epoxy and 403 fibers for wood
construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509.
VariViggen welded nose and main landing gear, 1-1/4"
sq. steel tube.

BILL CAMPBELL (VariViggen builder), Box 253, Phelan,
Ca. 92371
VariViggen prefab brackets and fittings.

JESSE WRIGHT (VariViggen builder), 7221 S. Colorado
Ct, Littleton, Co 80122.
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot

report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing; 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

VARIVIGGEN CONSTRUCTION MANUAL Part 1 of a photo-illustrated construction manual, written by Jim Cavis, S/N 31. Includes fuselage, canard, inboard wing, vertical stabs, control system, and landing gear, along with approximately 100 photos. Part 1 also includes helpful sketches on jigs and numerous building tips. The written information

is similar to plans chapter 5, except expanded to about 30 pages.
Price: $18.50 first class mail, $20.50 airmail overseas.

THE CANARD PUSHER NO. 15 JAN 78

Published quarterly (Jan, Apr, July, Oct) by
RUTAN AIRCRAFT FACTORY
Bldg. 13, Mojave Airport
Mojave, Ca. 93501
(805) 824-2645

NEWSLETTER SUBSCRIPTION - $4.75 per year
OVERSEAS (AIRMAIL) - $6.50 per year
BACK ISSUES - $1.00 each

If you are building a VariViggen you must have newsletter 1 through 15. If you are building a VariEze you must have newsletter 10 through 15.

RAF ACTIVITY since the October '77 "Canard Pusher" has involved work on two new prototypes, new flight tests with the VariEze prototype - N4EZ, work with NASA on their VariEze evaluation and on the skewing AD-1, further evaluation of our solar water heater, builder support, a construction workshop, and preparation of "Section IV" (2nd edition) and "Section IIC" (Lycoming).

Those of you who are EAA members have already seen the Quickie in the January '78 "Sport Aviation." It is being developed as a joint venture by Burt Rutan, Tom Jewett and Gene Sheehan. Due to the large amount of time involved in supporting the VariEze program, Burt does not plan to market any new homebuilts in the foreseeable future; thus, after design freeze on the Quickie this spring, Burt and RAF will become inactive on the Quickie. It will be marketed as a complete kit (with engine) this summer by Quickie Enterprises, a new company formed by Tom and Gene. If you desire Quickie information beyond that in this newsletter, contact them, NOT RAF. They will stuff your self-addressed, stamped envelope with a Quickie flyer, or will provide a complete info kit for $6. (Quickie, Box 786, Mojave, Ca 93501.

The other project in our shop is still under construction and due to fly in April. It is RAF model 40, a light twin being developed for Pug Piper. He plans to certify and manufacture it within the next four years. Pug headed Piper Aircraft until 1974, then joined Beechcraft where he managed the group that developed the new Beech Model 77.

Our homebuilt solar water heating system has been in operation at RAF for about nine months now. When it has successfully demonstrated one year of operation we will be offering plans, and materials will be available at VariEze distributors. It is a very low-cost system using many of the techniques and materials used in the VariEze. It is designed to provide about 70% of the household water heating energy requirements at a cost of a small fraction of currently available units. Please do not inquire yet, but look for it to be available this spring or summer. Announcement will be made in the "Canard Pusher."

Clarance Langrond - first EZ in Texas (Austin)

Quickie prototype

NASA eval of N4EZ (Don Hughes, Phil Brown, Jim Patton)

AIRFORCE TO USE VARIEZE - Burt Rutan gave a series of canard design seminars to the Air Force Flight Dynamics Lab at Wright Patterson Air Force Base, Ohio. We just recently heard that they are now having a VariEze built to use as a flight test platform for some RPV avionics. It will have a pilot in the back seat and a lot of test gear in front.

CANADA VARIEZE APPROVAL - A seminar was held in Toronto, 1 December 77 to 3 December 77 for the purpose of evaluating inspection criteria for homebuilt inspection criteria for homebuilt composite aircraft. Attendees included Canadian D.O.T. management and inspectors from each of Canada's regional inspection offices. Presentations on composite structural design and inspection were given by Larry Haig (American Eaglet) and Burt Rutan (VariEze and VariViggen SP). Inspection discussion periods were held and workshops were given in which the inspectors were given first-hand knowledge of what is a good and bad part. This is something we would like to see in other countries!

We were pleased to see NASA's general aviation research activity take an interest in the stall/spin characteristics of the VariEze. Last November NASA Langley, sent pilots Jim Patton and Phil Brown and engineer Don Hughes to RAF to do a flight test evaluation of N4EZ. Their debriefing was positive. We look forward to seeing their formal report. Since their evaluation, NASA is going ahead with very comprehensive research including building two VariEzes, one for full-scale wind-tunnel tests and one for flight tests. They also plan small scale, spin tunnel tests.

The workshop on 18 December '77 at RAF was well attended by approximately 110 VariEze builders and guests. VariEze construction methods were detailed, and the beautiful weather allowed flight demos by the VariEze and Quickie.

VARIEZE CLUBS/SQUADRONS - Now that 25+ EZs are flying there is more interest in clubs. The following are new ones; see previous newsletters for others.

Omaha - Jud Bock, 11029 Franklin St., Omaha, Ne. 68154

Idaho - Kieth McIntyre, 923 1/2 Kenneth, Moscow, Id. 83843 (208) 882-4070

Ohio, In, Mi, Il, Mo - Paul Sunday, 666 Tyler, Peru, In 46970 (317) 472-1521

New Jersey - Lee Herron, 1480 Pleasant Valley Way, #12, West Orange, NJ 07052 (now has helpful newsletter, plans an EZ flying Jun 3-4, 78.)

Buffalo - Don White, 54 Columbia St., Hamburg, NY 14075 (716) 649-6137

ENGINES - "Section IIC," Lycoming 0-235 installation for VariEze is now available. We were almost two months late on this due to late arrival of documentation from Air Sport and to some redesign being required.

N4EZ now has nearly 300 flight hours. Its 0-200A has 1500 hours since major overhaul. It has required no maintenance besides oil changes since it was installed in N4EZ two years ago. It rarely requires more than two flips to start. Oil temperature runs at 170 deg F. Cylinder heads run 420 degrees in a long climb, 360 degrees at cruise, and do not exceed 300 degrees on a continuous hot-day ground run. It has never had a starter while on N4EZ and its alternator was removed a year ago. These two holes were covered with 3/16" aluminum plates. My logbook shows that the starter failed twice on the previous owner and the alternator once, costing him over $400! As you know starters are not recommended on VariEzes. Only one has flown with a starter and that builder has since removed it. About 1/2 of the EZs to initially fly with alternators have removed them also, to reduce weight. We strongly recommend that you first fly without starter and without alternator. Add them later if you desire but do initial flying as light as possible. Do use a carb accelerator pump or primer for easy starting.

The following is a quote from Warren Curd, Raytown, Mo: "I originally had full electrical - the airplane flew well enough, but I had to carry weight in the nose, then when I started adding weight in the passenger seat I was less than satisfied. I finally took your advice and removed the starter, alternator, two solenoids, 22 ft of 1/0 cable and heavy battery - weight reduction 65 lb! The airplane now flies and handles so much better, I hardly can believe it. TO & Ldg speeds & distance are greatly reduced, climb improvement is amazing -- take it from me, save yourself a lot of work later - don't install a starter or alternator in your Eze. Starting is easy and the trickle charger keeps the small battery sufficiently charged for radio needs."

One Eze flyer experienced sufficient clogging of his fuel filter at 35 hr to affect engine operation. The "Owners Manual" 1st edition recommended inspection at 50-hour intervals. We now recommend 25-hour inspections. In addition, check it after the first five hours for fuel tank contamination. If you are using the VA6 filter, replace, rather than clean, the element. One builder substituted a drain-equipped gascolator for the filter and drain, as he was concerned about the filter's ability to pass water. We know of no water related problems, but don't see anything wrong with his modification.

Some builders are reporting that their Westburg tachs don't function correctly - be sure you have the right model number - it should have an "M" on the end (for magneto). If yours doesn't operate I'm told you can send it with $2 to Westburg for modification.

MUFFLERS - N4EZ has been flying with mufflers since October. It has undergone modification to increase power, however net performance loss, due mostly to the aerodynamic drag of the large bumps on the cowling, is about four to five mph. The most disappointing news is that the net lowering of sound level is less than hoped for. The engine exhaust

noise is reduced substantially, but the prop noise and canopy air leakage is still there, making the Eze still louder than the average lightplane. Measurements taken at the front seat are shown below: Back seat, is one to two db louder.

VariEze no mufflers	75% pwr	98.5 db
VariEze mufflers	75% pwr	96.5 db
VariEze no mufflers	50% pwr	95 db
VariEze mufflers	50% pwr	93.5 db
Cessna-150	75% pwr	93.5 db
Piper PA28-140	75% pwr	91 db

Based on this data we have not yet decided to pursue production of the mufflers - we would like to hear from you builders to see if you would be willing to pay the cost, weight and performance penalty for this much reduction in noise. Let us know.

ROSENHAN WHEELS & BRAKES - Good news - the modification designed by the manufacturer has been tested by Lee Herron on his VariEze and he reports the new brakes are excellent. They use the same piston size as the Clevelands, do not require adjustment and are no longer "soft" as were the original ones. All brakes delivered after November '77 have the new direct-action calipers. If you want to update your original triangle-block type brakes, you can get a modification kit at VariEze distributors.

The previous Rosenhan brakes were supplied with neoprene O-rings which were supposed to be compatible with aircraft or automotive fluid. Fred Rosenhan has told us that some may swell with certain types of fluid. The new brake retro-fit kit has aircraft type O-rings and extra ones to change your master cylinders. If you experience swelling with the old type write Fred Rosenhan, 810 E. 6400 S, Salt Lake City, Ut 84107 to get a replacement of aircraft type O-rings.

STALL CHARACTERISTICS & CG - Bill Rogers has reported less desirable stall characteristics than N4EZ's. Specifically, his airplane would depart into a snap roll if aggravated with rudder at full aft stick, and could enter a very high angle-of-attack deep stall. This stall was easily recovered with forward stick. He flew his airplane to RAF; we installed some nose weight and he repeated his tests. This time his Eze responded similar to N4EZ at aft cg. Until we confirm his cg by an accurate weighing (he did his on bathroom scales) we must assume that he was aft of the aft cg limit when he discovered the undesirable traits. We recommend that you avoid the last inch of the cg range until you are well familiar with the stall characteristics of your airplane and know that your weight and balance is accurate and current.

VARIEZE PERFORMANCE - In an earlier "CP" we told you the rpm data supplied was in error. We have calibrated a backup tach and remeasured this data. See below. Note that Cassady has reduced the pitch on his VariEze prop to make it turn faster to help takeoff and climb.

Seal cowling leaks around the fuselage, exhaust and aileron tubes. Air leaks here slow the airplane and reduce cooling. Canopy air leaks can also reduce performance.

Your owners manual shows most data vs. density altitude. Add the chart shown below to determine this. The new 2nd edition of the "Owners Manual" has refined data based on N4EZ tests with wheel pants, and data supplied by homebuilders. In addition to cruise data it has full throttle speeds vs. altitude, allowing you to directly compare your Eze to N4EZ.

Recently we obtained an accurate fuel flow totalizer to better define actual inflight mileage. The results of these tests show that, due to the poor fuel specifics of the 0-200 at low power, the "Owners Manual" data is incorrect except at high speed. Cut out the graphs shown below and paste them in your owners manual to correct this (2nd edition has blank pages in back). The climb-fuel used-chart is handy for flight planning. All cruise data are for lean mixture, 25 degrees F on rich side of EGT peak. Our tests show that at 9000 ft, full rich mixture results in 21% decrease in range at 180 mph and 30% decrease at 110 mph! Even 25 degrees F extra richness (0.1" motion of mixture knob) causes 5 to 6% reduction in range.

GRAPHS AND CHARTS OMITTED

CP15, Page 3

CONTROL SYSTEM ROD ENDS - The HM3 rod ends used in the control system are susceptible to being damaged if you do not use care in installing them. When adjusting the pushrod under the front stick be sure the normal stops in roll are reached before a twisting load is applied to the rod end. Be careful to not bend the rod end threads. If an HM3 has been bent, twisted, damaged or overloaded in any way it must be discarded, or used in a noncritical area (landing brake for example). Check your rod ends, particularly in the pitch system where they are non-redundant - if they are marked HM3C return them to be replaced with HM3. The "C" is a commercial grade and is not as strong as the aircraft HM3.

This is the epoxy pump discussed on page 9. **PHOTO OMITTED**

CP15, Page 4

COMPOSITE STRUCTURE - It is evident from looking at some of the parts we've seen, that a few of you, including some inspectors, do not adequately understand the inspection criteria. We have even seen some parts that need repair to meet the criteria, yet they were passed by FAA. DO NOT assume that just because FAA signs it off, it is okay. DO assure yourself that you can judge a part to the criteria in "Section I," "Section V," and newsletter 10. Also, be familiar with the clarifications in the other newsletters. Some more follow:

Bump/Joggle/Dip Criteria - The best way to check this is to lay a 12-inch straight edge on the part spanwise. Move it all over the surface in the critical areas. If you can see 1/16" gap in any area, the part

must be repaired. It is best to repair or beef up lumpy areas even if they meet this criteria. Better yet, do a good job in core preparation and use your squeegee well in the lay up to avoid the lumps in the first place.

Dryness Criteria - Pick any 6"x6" square in the lay up in the critical area. Assess carefully if any evidence of air in the lay up is present (white flecks, bubbles, air at the foam face). If the dryness evidence is more than 10% of the area, the part MUST be rejected. Reject or repair any evidence of dryness or voids in the trailing edge or leading edge overlaps. Better yet, do an adequate inspection with good light before cure when it's easy to fix. If in doubt on overlaps be sure to stipple in enough epoxy.

The following is a listing of the "critical areas" - the portions of the VariEze that must meet all the inspection criteria:

1. Center section spar - entire outside skin and spar caps.
2. All portions of the fuselage within 10" of the engine mounts and canard lift tab attachments.
3. All control surfaces.
4. All flying surfaces in the shaded areas shown plus all overlaps at L.E. & T.E.

SKETCH OMITTED

Several builders have had flying surfaces warp or bend due to being poorly supported until fully cured. Do not hang or support them at each end for long periods as they may "creep" or slowly deform. Store them leading edge down with support in at least three places. Your surfaces can be better protected against "creep" if you post-cure them. Sailplane manufacturers do this by putting the entire airplane in an oven at 160 degrees F. You can do it as follows: After you have painted on the black primer put the wing/winglet or canard out in the sun - be sure it is well supported in at least three places along its span. At noon a black surface can reach 140 to 180 degrees F, giving it a relatively good post-cure. After the post-cure the structure is more stable for warping or creep. If you have a wing or canard that is twisted wrong, apply a twisting force in the opposite direction before and during the post-cure (weights applied to boards Bondoed or clamped to the surface can be used). Remove the force only after the surface has cooled. A 200-ft-lb torque (50-lb weight on a 4-ft arm) applied twice, once while the top surface is post-cured and once for the bottom surface, can twist your Eze wing or canard over one degree. The twist correction will be permanent and will stay as long as the surface remains cool (below the post-cure temperature). This is generally referred to as the heat deformation characteristic of the epoxy. If it is room-temperature cured only, it will soften above 140 degrees F. But if post-cured it will not soften until over 160 degrees F. Heat for post-curing or for intentional deforming can be applied by other means such as heat lamps, hair dryers or electric radiant heaters (household type), however this is generally not recommended, since it is too easy for the homebuilder to get the part too hot and ruin the part. The blue foam is damaged above 240 degrees F. If you want to use these heat sources, do so by applying the heat very slowly and checking the temperature often by placing your hand on the surface. If you can hold

your hand on the surface five seconds without pain, the temperature is okay - three seconds is too hot.

Most people think the relative incidence of the two wings, set in chapter 8 is permanent, with no adjustment. This is not true. Several builders, on our instruction, have used the heat deformation method to straighten wing incidence on a completed airplane as much as one degree to correct a poorly trimmed airplane. Do this as follows: Attach a board as shown to the wing to provide a 600-ft-lb torque in the direction desired. Cover the wing root with corrugated cardboard to insulate it to protect the blue foam. Using hair dryers or radiant heaters* slowly warm the center-section spar (three or four sides, depending on if fuel tank is on), continually checking the surface for correct temperature (at least five seconds to pain). Heat it uniformly from the wing fitting to the fuselage. Let the spar completely cool before removing the weights. Recheck incidence to see how much it changed - don't overdo it the first time, use only moderate heat until you see how much will be required. **SKETCH OMITTED**

Creep is rare on the main gear since this part is post-cured. However, the main gear is subjected to a continuous high stress over long periods when the airplane is parked. This stress can be greatly relieved if you lift under one wing and allow the gear legs to spring together, then set the airplane back down when you park it. It is doubtful if gear creep will be a problem with the Eze, but if you do notice creep (gradual spreading of the gear) it can be reset by pulling the wheels tightly together with a rope (weight off the gear)

* Do not use heat lamps - they can create hot spots.

---

heating then cooling the strut, then removing the rope. Another handy use of the heat deformation method is setting toe-in. If you need more toe-in, clamp boards on the wheels as shown, heat, then cool the strut, remove the boards and presto - toe-in that's easier than installing shim plates! **SKETCH OMITTED**

VARIEZE BUILDING HINTS - In order that you don't later overlook these, jot them down in the appropriate places in your "Section I." Same goes for building hints in other newsletters.

A builder has suggested a better method than the one shown in newsletter 13, pg 5, for building the eight glass pads in the wings and centersection spar at the wing fittings. The following method gives a wet bond of the pad to the wing fitting, saves a separate cure, and allows you to trim and round the pads at the sides, in-place on the fittings. First, measure dimension "A" to be sure it is .012" times the number of plies to be laid up in the pad. Dull the wing fitting, lay up the pads with excess hanging out the sides, no voids at front and back. Apply peel ply, then Saran Wrap (plastic release), then the block (overlapping the foam to assure a perfect transition from foam to pad), then the weight and let cure. Be sure to remove the peel ply and round the corners before the shear web is laid up. **SKETCH OMITTED**

Do not use a rod to align the CS2 brackets on the elevators. They can be as much as 0.1" off and a rod will still slip through and rotate freely. If you have done this, check by sighting or stringing a tight fine wire down the middle of the holes. The CS2 brackets must be repositioned if they do not meet the 1/16" alignment tolerance.

There has been some confusion on the sequence of applying the BID-wrap on the main gear. Lay the gear leg leading edge down on three blocks. Sand its surface and round the T.E. Apply one ply BID at 45 degrees. Cure. Turn over and apply 1-ply BID at 45 degrees. Now mount the tabs (step 2 & 3) then the brakelines (step 4). When glassing over the brakeline fill the adjacent void with dry micro. **SKETCH OMITTED**

We have been flying a different yaw trim knob on N4EZ that provides a finer adjustment, but eliminates the parking brake feature. This is optional; use it if you wish. Unless you can find some left-hand thread rod, it works backwards, i.e., turn it right for left trim. **SKETCHES OMITTED**

Many are still spending too much time in the layups. If a lay up takes over twice the time shown in the plans YOU ARE DOING SOMETHING WRONG and are probably not doing a good layup. Try this - instead of bringing in small amounts of epoxy to stipple in with a brush, pour the epoxy on the surface and make MANY LIGHT PASSES with a light squeegee to move the epoxy into the cloth. The squeegee can be the thin plastic from a coffee can lid. You can cut two 4-inch squeegees from the plastic cover of a 3-lb coffee can. It is easy to tell if the layup is too wet - pass the squeegee across the part then stop and lift it. If the lay up is too wet there will be a "lump" of epoxy where the squeegee stopped. Be sure resin is not colder than 75 degrees F. Using this method of going too rich, then squeegeeing the excess out gives less chance of trapping air. You will find this method works so fast that it is paced by measuring and mixing epoxy, so be sure to have one person who only does the mixing. Do a thorough job of inspecting for dryness, bubbles, overlap, imperfections, etc., and have someone else check it, too, before you leave it to cure. It's a shame to have to reject a part that's dry when it could have been fixed before cure.

Before glassing canard or wing bottom put masking tape below the knife trim line on the leading edge. This keeps epoxy off the foam on the top surface. A few pieces of 2"-thick, 2 ft-square foam rubber are handy to support wings and foam cores so they can be handled and worked on, without damage. Sticking nails into the leading edge of the wing cores at the W.L. at tip, root and mid-span will help in eyeballing the leading edge straight. Thanks, Duane Solberg, for the above hints.

Nat Puffer discovered that the canard bolts can be reached through the nose access door without need to reverse the bolts. He also suggests routing pitot line around, rather than under, battery to eliminate moisture trap.

Bob Gentry suggests adding 2" to the height of all wing jig blocks to give room to reach under to clean off micro.

Jim Smith reports a Sears model 315.17381 router is handy for recess cuts, rounding longeron edges and, set at zero depth, it removes excess

residual micro spots on foam and joints without cutting adjacent foam surfaces.

Make a drill jig as shown to accurately drill the hole through the outside pads of the main gear tabs. **SKETCH OMITTED**

CP15, Page 6

FLIGHT SAFETY - Most operational problems occurring with VariEzes have been due to not following the information provided in the "Owners Manual." It is disappointing to see someone fail to succeed solely because he overlooked or elected not to follow "the book." We do get questions from those who want to modify or exceed the limitations in the "Owners Manual." Our recommendation is to first follow the book; then if you desire, expand your envelope professionally to suit your needs, but DO NOT EXPECT SUCCESS, unless you follow all "Owners Manual" recommendations. Be sure you have completely updated your manual and checklist to include all newsletter additions (fuel system, ailerons, etc.) or buy the 2nd edition. Carry the book in your airplane. USE your checklist.

QUESTIONS - When writing RAF with an individual question please remember we can answer only those accompanied with a self-addressed, stamped envelope. If you're outside the U.S. you can substitute an international postal coupon (available at your post office) for the stamp.

Q. Can I use Scotch Brite dish pads to dull the fiberglass for a future layup?
A. No, use only 36-grit or 60-grit sandpaper. Better yet, plan ahead and use peel ply. We've noticed that many builders are not using peel ply for winglet attachment. Be sure to peel ply the outboard 18" of the wing and the lower 14" of the winglet.

Q. After installing the optional landing brake my left suitcase doesn't fit - what now?
A. Trim the stiffener from the suitcase front and cock its nose inward about 4".

Q. Can I hinge the instrument cover for access?
A. No, the piece behind F28 is structural and must be glassed in place as shown to aid fuselage stiffness.

Q. I hear different numbers - how much does it cost & how many man-hours to build an Eze?
A. This info is based on what we hear from builders. Those who buy all available prefab parts spend about $4900 + engine and average 900 man-hr. Those who build most everything spend about $3000 + engine and average 1400 man-hours. Minimums we've heard of are $2400 + engine and 580 man-hours.

Q. Instead of the separate fuselage fuel tank can I make my aft fuselage compartment into a fuel tank?
A. Yes. Several have done this, saving work and weight. The inside of the compartment must be laid up wet, like the wing tanks. The cap, outlet, screen & vent are installed similar to the wing tanks. The

tank must have a bottom as shown to allow wing tank vents to pass under & to avoid leaks at the center section spar bolts. **SKETCH OMITTED**

VARIEZE PLAN'S CHANGES - Be sure to copy these into your plans now.

OWNERS MANUAL (1st edition only) page 40	Change 50 hr to 25 hr. Add "replace element if VA6 filter is used."
OWNERS MANUAL 1st edition pg 20 2nd edition pg 19 also VariViggen Manual pg 16	Add "stall characteristics have been found to vary from airplane to airplane, particularly at far aft cg. Avoid the last one inch of the cg range until you know the stall characteristics of your airplane and know your weight and balance is current and accurate. Recovery controls for any unusual characteristics at high angle-of-attack are stick forward and rudder against any rotation, (ailerons neutral)."
OWNERS MANUAL (1st edition only) pg 4	Add the following: The diagram below shows the motion of the nosegear handle to extend or retract the gear. The handle is locked in the lowered position for gear up or down. Do not force the handle downward unless it is fully forward or fully aft. **SKETCH OMITTED** If the handle is forced down repeatedly this can bend the tube with the result that the down lock "snub" is lost. Be sure to check that the required one-inch snub is available. (Pg 17-10 of "Section I").
SECTION I Pg 17-10 & pg A-1	Revise the slot for the nose gear as shown below (straight slot). Fabricate the parts shown below and install as outlined on page 7 of newsletter 14. This eliminates the sideways motion of NG10, allowing NG11 to remain firmly in the extreme locations of NG13 guides. If NG11 is not fully into the extreme travel of NG13's on both sides, the nose gear may come out of its lock during taxi. **SKETCHES OMITTED**

SECTION I Pg 18-1	Ignore dimensions on landing gear tabs. Substitute those shown below. If you have fabricated these check to be sure you are not short on the 0.85 dimension. **SKETCHES OMITTED**
SECTION I	Beef up of landing gear attach tabs shown

Pg A-5 & pg 10-3	in newsletter 12 & 14 has required that some material be removed from the main gear strut to correctly fabricate the tabs. To avoid this, move both forward extrusions forward 0.2" and move both aft extrusions aft 0.2". Each extrusion set should be spaced 5/8" apart. (Initial fabrication only, retrofit is not required). Do not lay up pads on wax paper.
AILERON ADDENDUM page 5	Drawing on right side - 9-3/4 should be 9-1/4.
AILERON ADDENDUM page 9, Bill of materials	Add "6061-T6 can be substituted for 2024-T3 on the 3/4" tube.
SECTION I pg 15-1	3.7 should be 2.7
SECTION I pg 6-7	Section A-A trough should only be 8" long on bottom of wing. Use the full 10" for wing top. Use care to not undercut this area. On glass dimensions, increase the 58" dimension (UND spar cap) to 62" and increase the top UND spar cap from 62" to 66" (page 6-11). New construction only, retrofit is not required.
SECTION I pg 4-2, 6-1, & 7-1	Add "Be sure to use the method shown at the top right of pg 7 of newsletter 12. This will assure a straight leading edge. Hotwire L.E. wire
SECTION IIA & IIC	Add "mixture and throttle controls must operate smoothly without free play, lag or excess friction. They must snub against idle and full positions. Check this before running the engine."
SECTION I Pg 22-8 &	Reference the canopy opening occurrences described in newsletter 14. A builder has suggested a car-hood type secondary latch system that doubles as an engagement point for the canopy key lock. To open, use key to rotate lock arm vertical. Then raise canopy 1.5" and push in on the latch. I haven't installed this but it looks like it would work fine. **SKETCHES OMITTED**
OWNERS MANUAL Pg 40	In annual maintenance section add "Jack or lift the weight off the wheels and measure the spread of the main gear. If it's more than 56 inches at insides of strut at axles, move it inward using the method in newsletter 15." (see page 5). **SKETCH OMITTED**

SECTION I Pg 6-14 & 6-15	The waterline on template Y/B and the straightedge of jig block F are at an incorrect angle by about 0.7 degrees. This error was noted in newsletter 11, and builders were told to shim F to get straight leading and trailing edges. Most builders have done this, taking the correct approach of making the root & tip waterlines parallel and shimming to get a straight L.E. & T.E., thus getting a straight wing with the correct twist. However, some did not notice the note in cp 11, and have questioned us on the jigging method. To avoid confusion, correct the waterline on Y/B and F as shown, by raising them 0.27" at the trailing edge. They are correct at the leading edge. Now, if the jig blocks are mounted on a flat table, the L.E. & T.E. should be straight. **SKETCH OMITTED**

SHOPPING - Good news. Several of the items we have been trying to get on the market are now defined, tested and ordered by the distributors.

EPOXY PUMP - marketed by Aircraft Spruce & Wicks. This is the same pump we've been using at RAF for the last year. It dispenses the correct ratio of resin and hardener into a single cup. It is a well-built, industrial quality unit. It saves a lot of epoxy since you can make small batches if desired (the balance scale is not accurate below one-two oz.) It can save about 5-10% of the man-hours required for a layup. It should be durable enough to last for years of continuous use.

SOLAR PANEL - We have finally been able to get a manufacturer to build a solar charging panel for our application at a good cost. It is only 0.1" thick, weighs 0.6 lb, measures 9"x12" puts out 4 watts, and retails at Aircraft Spruce & Wicks for about $119. This panel can be bent into a gentle curve for mounting on the Eze nose.

PLACARDS - Aircraft Spruce is developing a complete set of metal placards for your Eze cockpit. They have a special sponge-type adhesive that adheres well to a fiberglass surface.

SPINNER - Aircraft Spruce now has a spinner specifically designed for the VariEze. It has been in test on N4EZ for the last three months. Previous spinners have suffered cracks after a few hours. This one has two very stiff flanges that accurately fit the cone. It has a long, pleasing shape, is 10.3" diameter, and comes complete with forward airflow guide for best engine cooling and low drag. I had given up on spinners until this one worked out so well. Specify engine type and prop hub thickness - the flange is custom trimmed.

4-PLY TIRES - Wicks and Aircraft Spruce are now stocking 4-ply main tires for the VariEze. They are lighter but stronger than the 2-ply

slicks. They have a fine tread that will not pick up large rocks. They should be operated at 65 to 70 psi pressure. I am using these now on N4EZ.

RUDDER & PITCH SPRINGS - Aircraft Spruce is now stocking custom-made springs for VariEze pitch trim and for rudder return.

PREFAB WINGS/CENTERSECTION SPAR - Jiran is currently completing tooling to produce VariEze wings and C/S spars. The design is somewhat different than the plans, in that a long tongue with two pins is used in place of the current metal fitting. This allows incidence adjustment. The wings will have a sailplane-like finish. They will be flight tested on an airplane built by Jiran for that purpose. That airplane will be sold after tests are completed. Anyone interested in it should contact Jiran.

"I FLY A VARIEZE" SIGN - Cowleys is making an attractive plastic magnetic sign - contact them if interested.

FOR SALE - A75-8.G. Layton (213) 894-3979.

FOR SALE - VariViggen wingfitting set, Lynn Pilkington, 140 S 1st W., Hyrum, Ut 84319, (801) 245-3805.

MATERIALS SUBSTITUTION - Those of you who receive "Sport Aviation" may have noticed an article in the January issue by Hans Neubert inferring that VariEzes could be built from commercial weave 181 and 143 fiberglass and any one of a number of commercial epoxy systems. Particularly disturbing was the author's inference that our distributors were merely pouring the low-cost, highly-toxic 815 resin into containers with a different label. We are not concerned that VariEze builders are being misled, as they have been kept aware of the reasons we had to resort to special formulations and cloth weaves. "CP" 10 (Oct '76) describes the problems we encountered trying to use 181/143 cloth and attempting to use Shell 815 resin systems. It also describes our fight to reduce the materials' cost. As we discussed in "CP" 12, development of the resin/hardener system after the first vendor went out of business, was a difficult, time-consuming task. This required five months of testing over 20 different formulations from three different vendors to develop a system that would meet our requested specifications of (1) min SPI of II, (2) heat distortion, (3) odor, (4) room temperature physicals, (5) fuel and foam compatibility (6) moisture absorption (7) cure time at 65 degrees and 95 degrees (8) exotherm with micro mix, in insulated foam core, (9) mix ratio, (10) viscosity, and (11) shelf life. It is of interest to note that one of the larger formulators in the Los Angeles area was unable to develop a system to simultaneously meet the requirements, and Applied Plastics required over a dozen different system variants to arrive at the solution. I have asked Applied Plastics, the RAE formulator, to respond to the Neubert article. Their comments follow:

"I believe it to be fairly well known that in early 77 the R A resin system was changed from the "Lambert Blend" to epoxy resin and hardeners manufactured by Applied Plastics Co. Inc, 612 E. Franklin, El Segundo, Calif. Applied Plastics is a resin manufacturer supplying the aircraft and aerospace industry world-wide and have been manufacturing chemical intermediates for more than twenty-five years.

Explaining the varied technical capabilities, unique abilities of our chemists and our extensive quality control department would be time consuming and may indicate an attitude of DEFENSE while to the contrary we are offensively incensed by this article which in our opinion does not take sufficient regard for the personal safety of fellow EAA builders and of others who might follow these suggestions. The statement that R A resins after March are the familiar Shell Epon 815, only further substantiates our feeling that substituting resin systems without laboratory evaluation by QUALIFIED INDIVIDUALS can be extremely dangerous. Our laboratory testing showed the use of B.G.E.

---

resins in this construction to cause extensive foam damage. Let me state here that Applied Plastics does not now, and never has, supplied Shell 815 or Shell 828 as R A resin. The cost comparison example which suggests you buy 828 by the drum is an extremely hazardous recommendation, in our opinion. The pages that address themselves to epoxy hardener substitutions are equally as potentially hazardous. The suggestion that would encourage a homebuilder to handle materials such as DETA and TETA are in our opinion reckless and unnecessary. The following hardeners were not usable because of the safety problems they represent; also our knowledge of working with these materials showed them to be too exothermic when used in foam cores with microballoons: AEP, TETA, SHELL U, SHELL T. Shell A was never considered as it is a system that requires heat curing and not too many have autoclaves or walk-in ovens, not to mention the added responsibilities heat-curing systems require to make good laminates. Shell T has been discontinued for well over a year. The chart which showed the above curing agents along with Versamid 140, which is a high viscosity material, and then suggested that you thin with toluene or alcohol can again produce a hazardous situation, hazardous when working with them as well as hazardous from the standpoint that you change the physical properties of the hardeners when you cut them with solvents. When solvents are trapped in laminates you will also get long term degradation of the laminate, and foam core damage. The development of the RAE slow hardener to meet the requirement of adequate cure and yet not result in exotherm damage deep in a foam core, required several months testing. More than a dozen different systems were tested, not merely to optimize the pot life but in fact to achieve a system that provided the homebuilder with a safe structure. Both the fast hardener and the slow hardener required numerous tests to meet the specifications. Often we would find material that would be excellent in all properties but then would fail to meet the all important heat resistance test. This requirement alone excluded most of the common base hardeners referred to in the article by Hans Neubert. Let me add that Applied Plastics sells most of its materials in drum quantities and would be most pleased to pass on savings through the distributors to builders who have the resources and the equipment necessary to handle five-hundred-pound drums. Finally, let me reiterate that from the beginning our intention was to provide safety and safety at a moderate cost; in our opinion the R A resin systems are sold at a very low cost for formulated systems."

I have invited Mr. Neubert to our shop for a first-hand demonstration of what happens when the VariEze layups are attempted with 181 and 143 cloth. While they perform nicely when used in vacuum bag operations they present unacceptable problems when used in most of the Eze hand-layups. We made many measurements of this when we originally attempted to use them. They can more than double some lay up times due to the frustration of chasing wrinkles and bubbles, they cannot be flagged for spar caps, they hide air making inspection more difficult and less reliable, they draw in air after a moderate pass with the squeegee, their ability to conform to compound curves is less than BID and UND, the difficulty in determining major fiber orientation leads to errors, and they require more resin to wet out for the inexperienced laminator, resulting in a weight increase.

Summarizing, we have spent a considerable amount of effort developing methods and materials to make it possible for the homebuilder to do what the aviation industry cannot yet do - that is, build a safe all-composite airplane. To allow the average individual to be capable of this task did require other than the commercially available materials. A VariEze with engine and radio will cost from $5000 to $10,000. Saving 3% of that by substituting unsafe structural materials is foolish.

VARIVIGGEN NEWS - (Be sure to note the "Owners Manual" addition shown on page 7 of this newsletter).

Another Viggen has taken to the air since "CP 14. Here are details from Harold Reiss.

"1st. flight C.G. was set up at 122.9" with a 180 lb. pilot, 15 gallons of fuel in the main tank and an empty weight of 1130 lbs. I had to add 47 1/2 lbs. of lead to the nose to get this C.G. location, so, other builders keep the tail end as light as you can without sacrificing strength, particularly if you locate the battery behind the front seat bulkhead, as I did.

Dec 27th runway taxi tests were somewhat limited. I had planned to do 4 or 5 runs down the runway to determine how it would handle, however the first nose wheel lift off at 47 indicated resulted in a somewhat mushy 1 to 2 ft. high flight. After putting it back on the runway, and while still rolling, I applied about 1/2 throttle to 52-54 indicated, retarded the throttle to idle to prevent further acceleration, raised the nose wheel and once again the mains followed and I found myself airborne at about 10 ft. Everything felt fine with the stick slightly aft of neutral and centered so I decided to go ahead. I applied about 1/2 throttle, climbed up to pattern altitude, left the gear down, and set up a normal approach. Had 20 degrees of crosswind at about 5 kts. and used diminishing power. The landing was a squeaker. There are no indications of any warps or twists in the flying surfaces so no trim tabs will be needed.

Thursday Dec. 29 - Actual planned first flight. Take off run was slightly long as I used only about 1/2-power and had about 18 kts wind at 190 degrees on runway 22 - crosswind control is excellent - flew the pattern with gear down and did a power approach landing which was again a squeaker and

slightly nose high. The nose fell through a lot slower than the first time and I taxied in to complete the T.V. coverage (six and 10 o'clock news) Then I decided another flight was the order of the day. I broke ground a lot quicker with full power at about 56 indicated and lowered the nose a bit. Speed build-up is very rapid in this airplane as it got to 120 ind. right now. Started up to pattern altitude, slowed to 80 - 95 and retracted the gear, nose wheel first, by using the panel breakers, and then the mains. The gear came up perfectly though I did notice a slight vibration after retraction. Got on downwind, slowed and selected gear down - there went the nose wheel down and locked, but alas no mains - shook the wings - still NO MAINS. I then cycled the circuit breaker for the mains and had NORMAL gear extension.

I suppose the breaker might have opened at a lower than 5 amp current draw during retraction and took that long to cool for reset, although I think everything was all the way up. During tests on the jacks I had checked the load electrically and found it to be 3.57 amps with no outboard load on the wheels. So far the airplane has about one hour of actual flight time on it and it feels really good. If we had some of your California weather instead of snow every day, the time on 29HR would build faster. I called Mike Melvill and we will get together for some photos when the weather is decent."

Mike has also had the main gear C/B pop. We are recommending that you change both main and nose breakers from 5 amp to 7 or 10 amp. Mike installed cabin heat per the instructions supplied with the cowl. He reports that it is very effective with more than enough heat. He has floor outlets in both cockpits and on the windshield.

Mike had a very harrowing experience with his Viggen at about 50 hr. Apparently due to a materials defect a 1 ft length of one exhaust pipe fell off and hit the prop causing 1/2 of one blade to separate. The resulting severe vibration made the wing tips invisible and set off the ELT. Mike shut down and made a forced landing in a field. No damage resulted except for prop and pipe. Mike was quite complimentary on the strength of his Viggen to hold up under this severe shaking. He replaced the defective part and installed a stainless "net" on the cowl outlet such that a reoccurrence would allow the tube to drop into the cowl rather than the prop. He also shortened his tubes to the same length as N27VV's. N27VV ran this exhaust system (in mild steel) over 500 hr with no indications of any type failure. Mike now has nearly 100 hr and plans to fly to the sun-n-fun flyin in Florida this month.

The accompanying photos show the progress of Dave Burdette's all composite canard for his Viggen. Also shown is Ken Guscott's winglet installation on a standard-shaped composite wing.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

VariViggen glass canard in jig.

Jim Smith, Dave Burdette

No! This canard goes on the Viggen, not the EZ!

Ken's winglets.

QUICKIE - The photos give you a good idea of its configuration. You EZ builders will find its structure very familiar, except that it has no wing fittings - its canard & wing are made in one piece & built permanently on the fuselage. We use the term "2/3 EZ" a lot, since it has about 2/3 the glass and epoxy of an EZ and takes about 2/3 the man-hours and cost to build. Its empty weight is much less than 1/2 the EZ's and it has only 16 or 18 horsepower! It will cruise comfortably over 110 mph and has good range. Burt did the initial 3-view in May 77. Tom, Gene and Burt worked on drawings and engine development during June and July. Construction started in late August 77. It was kept a secret from all but those of us at RAF until its first flight in mid-November. The airplane is described in great detail in Quickie Enterprises "Info Kit." Please do not call or write RAF for info on the Quickie - as Tom and Gene will be doing all marketing and homebuilder support. Those of you who will build the Quickie are in for a real pleasant surprise - this is one, fun airplane to fly!
PHOTO OMITTED

NEW RAF LIGHT TWIN - Shown in the adjacent artist's concept is our 4+2 twin under construction at RAF. It will be in a class by itself, in that it is a very basic airplane with few complex systems and is considerably lighter than the competition. Its 46-inch wide cabin is more comfortable and has 6" more leg room than current light twins, yet its overall size, gross weight, and wing area is much less. Its primary intended attribute is safety, in that it not only has no min-control speed, but will require no pilot action or configuration changes in order to climb when an engine fails. It is designed to even be able to climb at its minimum full-aft-stick speed, at gross, with one prop windmilling (not feathered) and with the gear down. A comparison follows. Note that the M40 has retractable nose gear only, no flaps and fixed props. Both airplanes have two 160-hp Lycomings.

	GRUMMAN COUGAR	RAF MODEL40
Seats	4	4+2
Span	36' 10"	28' 10"

PHOTOS OF QUICKIE AND DRAWING OF MODEL 40 (DEFIANT) OMITTED

VARIEZE

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6',5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance. THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive

tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP AT GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	560 lb
Gross Weight	1050 lb
Range at Max Cruise	700 mi
Range at Econ Cruise	850 mi
Min Speed (full aft stick)	55 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6 square feet
Canard Span/Area	12.5'/13 square feet

SPECS & PERFORMANCE WITH 75-HP CONTINENTAL:

Take Off	1050 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	530 lb
Gross Weight	950 lb

THE FOLLOWING ARE RAF-AUTHORIZED DISTRIBUTORS OF VARIEZE MATERIALS AND COMPONENTS. CONTACT THE DISTRIBUTORS AT THE ADDRESSES SHOWN FOR THEIR CATALOGUES AND DESCRIPTION OF ITEMS.

AIRCRAFT SPRUCE & SPECIALTY CO. OR WICKS AIRCRAFT SUPPLY

OVERSEAS (AIRMAIL) - $6.50 per year
BACK ISSUES - $1.00 each

If you are building a VariViggen you must have newsletter 1 through 15. If you are building a VariEze you must have newsletter 10 through 16.

RAF ACTIVITY since the January 1977 newsletter has involved finishing the test program on the Quickie, construction on the M40 twin, homebuilder support, further evaluation of our solar water heater, consulting on the AD-1, and further flight tests with our VariEzes.

QUICKIE - The Quickie finished its very thorough flight test program on 14 April 78, five months after first flight. Although the Quickie flew well on its first flight it underwent some configuration modifications during its test program. These included an increase in aspect ratio and span of both the canard and wing, and modification of its ground attitude to optimize takeoff and landing qualities. Its flight test program, conducted at RAF, was done jointly by Tom Jewett, Gene Sheehan, and Burt Rutan. Gene did the majority of the construction work, Burt the design definition, Tom the drawings. All three shared test pilot duties with Burt doing all envelope expansion except the last two spin-attempt flights. Peter Lert flew the last spin attempts - he had done the VariEze spin test two years ago. Tom and Gene have now formed Quickie Aircraft Company, Inc. and plan to have the Quickie kit on the market before June. Their address is Building 68, Mojave Airport, Box 786, Mojave, Ca. 93501. Please contact them, not RAF, for any information on the Quickie. Two aviation writers have now flown the Quickie. Their articles will appear in the June issues of "Air Progress" and "Flying" magazines. Some interesting facts about the Quickie follow:

Maximum sea level speed is 126-mph, cruise at 75% is 115 - This is over 6-mph per horsepower, a considerably higher ratio than any available airplane.

Even though the Quickie has only 18 HP it has no 'sink' or 'mush' on the back side of the power curve. When it is flying at full-aft-stick at 53 mph it 'bucks' or bobs its nose up and down. At this full-aft-stick condition it can maintain altitude at 10,000 ft and can climb 300 ft/min at sea level!

Its total wing area is about the same as the aft wing of the VariEze, 53.8 sq. ft., yet it can heft a 180-lb pilot and 20-lb baggage off the ground at 53 mph and fly him over 600 miles at 100 mph.

The Quickie is characteristically incapable of spinning; its high angle-of-attack flying qualities are identical to the standard-wing VariViggen - docile enough that the pilot does not hesitate to make very tight turns near the ground without fear of stall/spin.

The RAF hangar is located on the west end of the flight line at the Mojave airport, Mojave Calif, approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any part for our comments. We are normally open from 9 to 12 and 2 to 5 on wed thru sat, but you should call first to check, since with the fly-in season starting we will be gone a lot. We plan to fly N4EZ to the Chino, Watsonville and Oshkosh fly-ins and possible some others.

When writing to RAF always send a stamped-self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder-question. Mark the outside of your envelope "builder question". This will speed our reply.

CP16, Page 1

MODEL 40 - Our light twin is now nearing completion, with engine controls, wiring and cowlings yet to be built. See "Canard Pusher" 15 for a description. Of particular interest is the airplane's estimated performance at light weights, i.e., one pilot and one-hour fuel. Weight for this condition is less than 1800 lb and weight-to-power ratio is only 5.6 lb/hp! At this weight we expect a climb of over 3000 fpm, 800 on one engine, with the other windmilling.

It is interesting to contemplate the impact on light twin safety that might occur with an airplane that has no large trim change and requires no pilot action at engine failure. Our design goal specifies absolutely no configuration changes or systems adjustment immediately required when an engine fails. Its throttles are combined into an unit that appears and feels as one grip, but is shaped to provide foreaft identification. Its fixed-pitch props dictate a normal cruise at 55% rather than 75% power, a wise fuel economy on all twins anyway. However, the 40 is expected to cruise over 10 kt faster at 55% than the competition at 75%, doing so at over 50% more miles per gallon! Of course, these are estimates at this point; we will know much more in a couple of months. The main reason we are telling you so much about an airplane that has yet to fly, is we need your help. We do not have a name for the Model 40 yet. So, we are having a 'Name the Plane' contest. Please send in your suggestions, addressing them to NAME THE PLANE CONTEST, c/o RAF, 13 Mojave, Airport, Mojave, Ca 93501. The winner will get a free five-year subscription to the "Canard Pusher." If possible the name should emphasize the safety, simplicity, or efficiency of the airplane, or its composite construction.

Please remember that the M40 was not intended for homebuilt construction. At this point it is considered only a proof-of-concept prototype. We are not in a position to answer questions about its future application. We will keep you informed through this newsletter of test results and future plans.

DID YOU KNOW??? That the VariEze on the cover of the April "Air Progress" is owned by Dianne and Lee Herron. They flew two hours of formation photo work to get the beautiful photos used in the article, but were not even mentioned in the magazine. Another unusual item about their coverage is that some very lengthy discussions of the VariEze's flying qualities were written by a pilot who flew one for only a few minutes and made only one landing. The managing editor of "Air Progress" has flown at least 20 flights in two different VariEzes including cross-country flights and spin attempts, yet printed no comments about his flights.

COMPOSITE INTRODUCTION PACKAGE - We are in the process of preparing an introductory kit for those contemplating building a VariEze, Quickie, or VariViggen SP wing. This will be a kit of sample materials (epoxy, glass, foam, peel ply, micro, cups, brushes, etc.) and a booklet describing the use of foam and glass in moldless aircraft construction and plans for several items to build with the sample materials. The purpose of the kit is to, at low cost, help you answer the questions: "Can I build a glass airplane?" or "Do I enjoy working with the materials?" The booklet contains all details about how the materials are applied in moldless composite sandwich construction. Also, detailed is information teaching you how to inspect for flaws and how to repair them. The kit will be available direct from Aircraft Spruce or Wicks (not RAF) about the first of June. Contact them at that time for price and availability (addresses are enclosed within).

VARIEZE/VARIVIGGEN CLUBS -
Lee Herron, Box 357 WOB, West Orange, NJ 07052, (201) 736-9092, has asked that Easterners planning to fly Ezes or Viggins to Oshkosh, contact him to arrange a formation flight, or pickup along the way. By the way, Lee has put light-weight Slick mags and removed the generator from his "Dragon Fly" Eze and reports, "The change in performance is fantastic. Climbs like a dragon with its @#$#% on fire!" He also is using an 0-200 carb on his C-90. Lee is planning a flyin on 3 and 4 June at the Essex County Airport.

Bernard Dodd, 193 Earlscourt Ave, Toronto, Ontario, CANADA M6E 4B2 (416) 651-2555 is EAA chapter 41 designee in composition structures, and is now organizing a Canada VariEze club/squadron. All Canadian builders contact Bernard; he can give you all valuable help with your projects; he attended the December 77 Canadian composite symposium.

CANADA APPROVES VARIEZE - The Canadian DOT has approved the VariEze for Canadian homebuilders. We would like to express our appreciation to the following individuals, and to others who worked so hard to organize the December 77 composite symposium: K.D. Owen, Chief Airworthiness, Inspection, DOT; W.E. Slack, EAAC Tech Committee Chairman; Eric Taada, EAAC, Ottowa, Ontario; Gogi Gogiullett, EAAC President; H.J. Bell-Walker, DOT; George Gibbons, Wicks Aircraft Supplies.

JIRAN MOUNTED CANOPY
Jiran reports that some of you are confused on the use of the mounted canopy assembly. The mounted canopy as supplied is located with the front of the glass frame at FS28. To do this you may have to remove some foam. The rear of the frame DOES NOT reach the firewall.

You may locate the mounted canopy any place on the fuselage should you wish to change the position of the transparent part to suit your particular needs for visibility, up to 2" forward of the position shown in the plans. Do not forget to install all inserts at the correct place to fit the hinge and latches on your fuselage, before glassing the inside. Be sure to clamp the frame to the correct width before glassing the inside.

Trim the rear of the frame as per your plans. The missing part between the mounted canopy and the firewall must be constructed by you into a fuel tank as per "CP" 16.

Cut the front of the frame as per the plans to provide the movable part of the canopy.

The section from FS28 to the movable part of the canopy may be used if desired, but MUST be glassed inside and glassed to the fuselage per the plans to provide fuselage stiffness.

If in doubt, follow "Section I" chapter 22 and make your finished canopy STRUCTURALLY IDENTICAL. The finished outside frame as received has the same number of plies as the plans.

SURVEY OF EZs AND VIGGENS NOW FLYING
We are often asked how many homebuilt EZ's and Viggens are flying and what has been their operational experience and performance. Since we do not have a complete list of this information, we are asking all of you now flying to fill out the form below. In most cases it will require you to do a flight to gather the performance data. The correct method to do this is outlined below. Be sure to send this to RAF especially if you have logged more than 100 hours, as we need this information for Australian homebuilt approval. The results of this survey will be printed in a future "CP" newsletter.

HOW TO DO PERFORMANCE TESTS - Easiest way to measure takeoff distance is to count runway lights. They are generally 200 ft apart - check to be sure. First, line up on the runway and center the nose gear so brake steering will not be required. Raise the nose slightly at 50 knots and lift off at the speed shown in the "Owners Manual" (depends on weight).

Measure climb rate not with a climb indicator, but by timing a 1000 ft increment with a watch. Stabilize at climb speed 1000 ft below aim altitude. Time from 500 below to 500 ft above aim altitude. Repeat several times. Do only in smooth air. Divide 1000 by time to get climb rate. Measure OAT (outside air temp) at aim altitude.

Speed determination is one of the hardest tests to fly since it requires patience and a fine touch. Be sure the air is smooth, record weight and OAT. Set the power, then hold altitude exactly for at least a full minute then note airspeed, now, increase airspeed one or two knots and confirm that after 30 seconds you are losing altitude. Then decrease airspeed to one or two knots below the target and confirm that you are slowly gaining altitude. If both happen, then the target speed is correct. Be sure to note rpm at target speed.

Room permitting we will present data reduction techniques for weight and temperature corrections and for correcting to standard day conditions in a future "CP".

PROPELLERS - Good news for those who have found an unacceptable backlog on props. We have flown another vendor's prop and found it performs very close to Ted's prop, same climb and only one or two mph slower speed. It is a 56x69 wood prop for Cont 0-200 by B & T Props, 8746 Ventura Ave, Ventura, Ca 93001 (805) 649-2721. They will also make C85 and C90 props.

We have found that many of you do not know how to balance a prop. This is necessary should you need to repair a rock nick, etc. It's also a good idea to check balance on a new prop. Slip a tightfitting tube through the center hole of your prop, long enough to stick out 1" each side. Place the prop across two level edges as shown and note which blade rotates down. Reverse the prop 180 degrees to check for

imperfect level of the edges. If you have questions on how much prop damage can be repaired, check with the prop manufacturer. When installing your prop, torque to 180 inch-pounds and check that tips track within 1/10-inch. **SKETCH OMITTED**

CANARD SURFACE SMOOTHNESS IS CRITICAL - During the Quickie program we built and installed a canard that resulted in very poor low-speed performance. Stall speed was 10 mph higher than predicted and tuft tests showed stall angle-of-attack over three degrees lower than estimated. We later traced the problem to a wavy upper surface. Since the EZ uses the same GU 25-5(11)8 airfoil, we suspected that it, too, may be susceptible to small roughness or waviness. So we tufted N4EZ's canard and put on strips of tape in various locations to simulate a wavy surface. These tests and other wind tunnel tests we conducted confirmed THE TOP SURFACE OF YOUR CANARD MUST BE SMOOTH FROM THE LEADING EDGE BACK TO AT LEAST 6-INCHES FROM THE LEADING EDGE or stall speeds may be increased and stall characteristics degraded.

Of course, the big question is "how smooth?" The best way to check this is with a steel pocket ruler, the flexible kind that's only .02" thick, or with a plastic drafting ruler. Hold the ruler as shown in the sketch, pushing it to the surface with two fingers 2 inches apart. If the surface is a smooth curve between your two fingers the ruler will lay down following the curve with no gaps. If the surface is bumpy or wavy the ruler will touch the surface only in 3 or 4 places. Take a feeler gauge to measure the gaps between the ruler and your surface. If you have a gap of more than .006-inch your surface is too wavy. Check this in several places from the leading edge back to 50% chord. The bad Quickie wing had gaps of about .012 inch. After refinishing (Featherfil, 70S, and white lacquer) with gaps of less than .004-inch, its stall angle of attack increased from 8 degrees to 12 degrees! VariEze N4EZ has gaps less than .003-inch.

The best time to use the ruler and check for smooth surface is when sanding the Featherfil with the spline. Recheck after sanding the 70S black primer. It will not change when white paint is sprayed on. **SKETCH OMITTED**

If your VariEze is now flying you can see the airflow easily and dramatically by tufting your aircraft as shown in the sketch. All tufts are 3-inch long strands of light yarn held to the airplane with a small dab of masking tape.

When the airflow is smooth the tuft will lie down steady. When stall occurs the tufts in the stalled area will shake violently or change direction. Refer to the sketch showing stall patterns indicated by tufts on N4EZ, flying at 950-lb gross weight. Above 53 knots (61 mph) all tufts are steady. Between 53 knots and 51 knots (59mph) tufts shake on the canard at the "A" area. Between 51 knots and 48 knots (55 mph) when the aircraft "bucks" the tufts shake on the canard in the "B" area, and at mid or aft cg when the aircraft exhibits "wing rock" (see "Owners Manual") the tufts shake on the aft wing in the "C" area.

So, by tufting your airplane and flying at 950 lb weight you can note the tuft patterns and airspeeds and thus compare your airplane to N4EZ. If your speeds are different it could be due to airspeed position or indicator error. If your tuft patterns are different it is likely due

to variances in airfoil smoothness. Also, if your tuft patterns are different you can expect that your stall characteristics will be different than N4EZ's. **SKETCHES OMITTED**

Gene, Burt & Tom with "windtunnel" rig to check effects of surface roughness of the GU25-5(11)8 airfoil. **PHOTO OMITTED**

VARIEZE ENGINES - Most EZs now flying are using A75, C85, C90 or 0-200 Continentals. There are three or four flying with stripped Lycoming 0-235 engines. Peter Krauss, of Stuttgart, Germany has now installed a 2600-cc, 85 HP Limbach engine (German) and reports 1600 fpm climb (1 seat), 1200 fpm climb (2 seat), and 190 mph max cruise. At 140 mph he burns 3.2 gal/hr. Our original prototype with the 1834-cc VW engine (N7EZ) has recently undergone its seventh overhaul or major engine repair, three within its last 40-hr flying. We are looking for a 60-hp Franklin to replace this engine.

VARIEZE FUEL SYSTEM - Some foreign-built VariEzes have had to change fuel lines aft of the firewall to fire-resistant material in order to obtain flight approval. USA FAR23 also requires this for a certified airplane but it does not apply to an experimental aircraft. We chose to use the low temperature Tygothane material to save cost and weight and did so because we feel the fire risk is low with a reverse-flow cooling system. Refer to the two sketches. A conventional aircraft has airflow from the engine and exhaust system blasting at the firewall. The VariEze airflow is such that the source of fire is blown up and aft, away from fuel lines and firewall.

It is possible that you, the aircraft builder, may not agree with us and may want to install your fuel system to meet FAR 23. This is your decision, of course, as you are responsible for the quality control of your airplane. If you want your system to be fire-resistant install Aeroquip 601 hose with 624 sleeve in place of the Tygothane aft of the firewall. Also, you may consider using a gascolator in place of the filter and drain. This costs more, but results in a more positive and frequent removal of sediment when you drain the gascolators on each preflight.

FAR 23 also requires steel, rather than aluminum, be used on primary controls that pass aft of the firewall. Again, since the direction of the airflow directs a fire source away rather than at these areas, we elected to save cost, weight, and building time by using aluminum. If you desire to comply with FAR 23, you may decide to make some aileron control parts from steel and accept the weight and cost penalty. We will continue to fly N4EZ with the configuration exactly as shown in the plans. **SKETCHES OMITTED**

VARIEZE NOSEGEAR FAILURES - There have been several failures of the NG1 strut where it bolts to NG15. It would be easy for us to dismiss this as a problem, since all failures we have seen can be traced to an incorrectly-placed bolt or failure to install the BID on the strut, and we have had no failure with N4EZ after 500 landings, some on rough fields. However, after closely studying this area we do admit it needs

improvement. The modification shown below should be incorporated. It should be done even if the gear has already been installed. The modification involves using a "U"-shaped steel bracket that captures the strut and eliminates the holes through the NG-1 strut. Thus, the full strength of NG-1 can be achieved, greatly reducing the chance of its failure. **SKETCHES OMITTED**

First, here's the best way to apply the BID wrap on the lower end of the strut. Refer to the sketches. Note that 1 ply BID should extend 10" up from the end and a second ply extends up 7". Be sure you have shaped the strut to perfectly fit the rounded slot in NG15, leaving room for the two plies of BID. The best way to get the BID to wrap completely around the strut without bubbles is to do it in two steps. First round all four corners then epoxy the BID only to the forward face and let cure. Then wet it out onto the other three faces overlapping the forward face. If it will not lay flat all around, wrap it with duct-tape or masking tape to hold it during cure.

Now, fabricate (or check if Brock has it in stock, yet) the steel "U" bracket, NG25. Fit the NG1 strut into NG15, and file off the bevel in NG15 to allow NG25 to slide all the way on and rest against NG1 full length. Clamp together and drill two #12 holes through NG25 and NG15 as shown. Note the holes must be drilled in the correct positions to miss NG1 and to miss the pivot hole. Disassemble, sand surfaces dull, and assemble with plenty of flox, installing the two AN3-20A bolts before cure. The nose gear door attaches to the two NG26 brackets; they bolt to the upper AN3-20A and rivet to the door with 1/8" pop rivets. **SKETCHES OMITTED**

SKETCHES FROM ARTICLE ON PREVIOUS PAGE OMITTED

WHEELS AND BRAKES - Many EZs are now flying with the modified Rosenhan brakes, all with satisfactory results. The original Rosenhan brake system is still proving to be inadequate in most cases. If you have the original Rosenhan brakes (with the triangle pad), install the retrofit kit before you taxi/fly. One builder had excessive dragging and heat buildup doing taxi tests with the original system. He had tight-fitting wheel pants installed so the excessive heat could not escape. The heat buildup was enough to soften the epoxy in the gear strut, allowing it to distort. A good solution for this is to use phenolic, not aluminum for the 1/8" spacer required at the strut (Rosenhan only) to provide insulation. Remove wheel pants for initial taxi tests when a lot of repeated braking is done.

We are recommending that you install a short length of brass or steel tubing in the ends of the Nylaflow tubing where they fit into the fittings at the brake and master cylinder. With the tube installed, the fitting makes a better clamp on the nylon line allowing higher pressures. See sketch. The tube (four req'd) is 1/8" dia, .02 wall, 1/2 inch long. It can be cut from the one-foot length pieces of telescoping tubing found at any hobby shop. Round the ends so they do not cut into the nylon tubing. **SKETCH OMITTED**

VARIEZE OR VARIVIGGEN SP PAINT COLORS - We have seen some violations of the "white only" recommendations in "Section V." One airplane has even been painted with a wide red stripe down the leading edge of the wings! This may cause serious heat distortion if this airplane is parked in strong sunlight on a hot day with no wind. The temperature of the red area will run 50 degrees F hotter than the adjacent white. Remember, all glass sailplanes are white only. Trim colors, particularly hot ones (see "Section V"), must be limited to vertical or underside surfaces, and never used across the top of wings or canard.

VARIEZE FOAM CORES - Recently, the manufacturer of the styrofoam used in the VariEze stopped making this material in the large 9-inch x 18-inch blocks. Since these blocks are no longer available, you are being supplied with blocks measuring 7-inch x 14-inch. These cannot be used as efficiently as the large blocks, thus, there is more waste and the blocks indicated below result in a total foam volume about 50-board-feet more than the previous sizes. The kit now consists of the following:

2 pieces 7" x 14" x 41"
8 pieces 7" x 14" x 64"

The information supplied below is intended to show you how to modify the procedures in the VariEze plans to obtain the correct parts from the ten smaller blocks.

CHAPTER 4 & 5, CANARD AND ELEVATORS:
Cut the canard and elevators as shown below from the two 41-inch pieces (trimmed to 40"). Save the large end of these blocks, they are needed in chapter 6 for the leading edges of the inboard wing cores. CHAPTER 6, WINGS:

Join the 64-inch pieces in four pairs as shown below and trim the 18-1/2 degree lines to the 53.25" trailing edge dimension. Square the ends, carefully measure the 9.37" dimension, and hot-wire the diagonal cuts. Add the scrap from the canard as shown to two of the pairs for sufficient foam for the large inboard cores using care to assure you don't make two left wings and that the leading edges sweep AFT, cut the four wing cores.

CHAPTER 7, WINGLETS:
Sufficient foam remains in the outboard core scraps to make winglets.

SKETCH OMITTED

CP16, Page 6

WING CORE SETUP - Trailing edge is at bottom on all four assembly drawings shown below. Templates are all placed upright. L/H are reverse of R/H. **SKETCHES OMITTED**

VARIEZE BUILDING HINTS - This simple jig will allow you to find the blind holes in the canard inserts after you have glassed the shear web and reinforcements. When installing the inserts, bolt them to a scrap piece of metal that nails to a board on each side, Bondoed to the

table. Remove the strip of metal, and glass the shear web. After cure, reinstall the metal strip and use it as a guide to drill the glass. **SKETCHES OMITTED**

When drilling fiberglass you can get a cleaner hole without the drill grabbing if you hone the lip of your drill bit as shown, flattening the draft aft of the cutting lip. On large critical holes, such as the 1/2" holes in the main gear tabs, use a spotface rather than a drill bit, for a perfect hole.

The best material for electrical conduit in the wings is a handful of soda straws. Stretch one end a bit so it will fit over the next straw. Gang them together and micro them into the slot in the wing. They are very light and large enough to push wires through for trim, or as a backup slot should you ever have to replace the rudder Nylaflow tube.

Unless you have a 10 or 12-inch drill bit you should drill the engine mount holes in the aluminum extrusions before mounting them in the fuselage.

When you lay the peel ply into the trailing edge notch before glassing the first side of wings, canard, and winglets, hold it in place as shown with a few tiny brads or staples so it doesn't move out of position when stippling the skin over it. **SKETCH OMITTED**

Up to now you have been using peel ply (Dacron surface tapes) only for preparing glass surfaces for future layups. During the Quickie program Gene discovered another use for peel ply that works so well we are using it extensively on the Model 40 and are strongly recommending that you use it on your VariEze as follows: In several places (winglet attach, fuel tank, cowling lip, nose, fuselage corner tapes) you have fiberglass plies terminating on the part, rather than on its edge. When this is done, the edge generally is rough causing a bump that must later

---

be carefully sanded. Also, (see sketch) unless the edge is loaded up with excess epoxy it can lift, causing the start of a delamination. Using peel ply over these edges, by stippling down a strip of Dacron across the edge (completely wet it out), will force the edge down eliminating the frazzled bump and providing a smooth transition of epoxy with no delaminating tendency. After cure, strip the peel ply off and you will have a beautiful joint with the glass edge almost invisible and with far less sanding required. Its hard to describe how well this works. Try it yourself and see. DO use it, particularly at winglet attach. It will make your cockpit more attractive if you use it to fair all corner tape edges. **SKETCH OMITTED**

Jim Smith reports that a "zippidi-Do" low cost cutting and sanding disc (available at hardware stores) does quick work grinding glass or Bondo when used in a high-speed drill or sanding motor.

Peel-ply the foam before the first lay up on the back-seat bulkhead, where the second lay up bonds to the first. Before the second lay up you can then strip this off and save sanding work.

Aileron hinges - be sure to reverse the piano hinge before cutting the lengths. If you are a little short of material subtract 1/2" from the length of the center or outboard hinge.

The following sketch shows a builder's suggestion for a simplified boarding step to replace the kick-in one. Calculations indicate less than 1-mph cruise speed penalty. **SKETCH OMITTED**

Some builders have experienced difficulty using Featherfill ("Section V"). Be sure the surface is dry, dull, and clean. Be sure the Featherfill and shop is at least 70 degrees F. Mix the catalyst thoroughly with a paddle or wire on your electric drill motor. After mixing catalyst, mix in about 25% by volume of microballoons, and brush on. Microballoons makes it go further, fill better, and sand easier.

Do not make the armrests removable. If you want better access around the stick, make a small removable panel locally where access is required.

Nat Puffer made up a bracket like the sketch below that mounts to the Brock throttle arm and provides attachment for a pushrod to a back seat throttle. This requires a hole in the inst. panel to clear it at idle, and simplifies installation of the gear-warning micro switch. **SKETCH OMITTED**

INSPECTION - We are still seeing some parts that have to be rejected because of flaws that could have easily been fixed before cure. Copy the following inspection summary. Post it in your shop. Read it before leaving any part to cure.

LAY UP INSPECTION CHECKLIST

1. Correct number of plies
   Correct type of plies
   Ply orientation within 15 degrees
   Ply wrinkles - free of major disruption
2. Surface condition - Smooth, free of joggles or bumps (measure with 12" straightedge span-wise)
3. Foam surface voids
   Uniform slurry, no visible air, no debonds
4. Air bubbles and white air flecks - none present
5. Lap joints - stipple and check for delaminations. TE and LE must be perfect.
6. Inclusions - FOD, brush bristles
7. Resin rich - Test with squeegee. Runs and pools removed.
8. Peel ply glass edge terminations or areas for later bond.

EPOXY MIX RATIO - Those who have purchased the ratio pump may have noticed that it is labeled "4 to 1" (25 parts to 100). This is by volume. Thus, due to different resin and hardener densities the pump actually ratios 22.5 parts to 100 by weight. The plans scale ratios 20 parts to 100 by weight. Our epoxy formulator advises that the acceptable range is 18 to 24 parts by weight and that it's best to be

on the hardener-rich side. So, we are changing the scale dimension for the hardener cup from 15 inches to 13.6 inches to obtain 22 parts to 100.

VARIEZE FUSELAGE TANK - Further clarification is required, since there are several ways to build this, some easier than others. The following method is easy, light, and makes use of your left-over 9mm, red PVC foam. Install the tank when you get to chapter 22, step 3. Do not install the urethane foam behind the plexiglass where the tank will go.

Cut the front and back bulkheads to fit the firewall and canopy, making the bottom in a "V"-shape as shown to allow the main tank vents to go under the fuselage tank. Cut the bottom pieces to fit and nail them in place. Now using a hair dryer, heat-form the curved top/side piece to fit the bulkheads and match the firewall and canopy. Remove the tank. Remove the front bulkhead. Bond the sides, bottom and rear bulkhead together with wet micro and lay up one ply BID inside. Install vent, outlet and screen. Glass the inside of the front bulkhead with 1 ply BID and micro it on the tank (use a strip of plastic tape on the foam where it will be removed for the sight gauge, to eliminate having to sand the surface later). When cured, round the corners and glass the entire outside surface of the tank with 1 ply BID. When cured, leak check using an altimeter and 1500-ft pressure differential. Drill a hole in the firewall to let the outlet through, then micro the tank in place, laying one ply over its outside, lapping onto the firewall and fuselage.

Install fuel cap. **SKETCHES OMITTED**

WINGLET ALIGNMENT - Some have had difficulty using the template and plumb bob to align the winglet to the wing. The following method is more accurate if measurements are taken carefully. It involves three measurements from a point at the wing root fitting to the winglet leading edge, trailing edge, and tip. Before trimming the piece from the winglet in step 1, set the root template on the root and transfer the chord line (waterline) up the leading edge as shown. When positioning the winglet on the wing in step 2 use dimensions A, B, and C instead of the positioning template and plumb bob. First measure dimension A from your mark on the winglet leading edge to the .063 aluminum plate (WA-6) on the aft side of your wing fitting. Make a mark on WA-6 where dimension A ends up. This mark is now used to measure dimension B to the bottom trailing edge of the rudder (held neutral) and to measure dimension C to the top trailing edge of the winglet. This accurately sets winglet incidence and outward 'cant.'

A = 108.3 inches

B = 117.0 inches

C = 126.0 inches

SKETCHES OMITTED

VARIEZE EXHAUST FAILURES - Bad news - The exhaust systems on VariEzes continue to be a problem. Recently, even the short system has failed, both with stainless and mild steel material. Data available to us on the entire history of EZ exhaust systems is shown below.

System	Number of Airplanes	History of Durability
1	1(N4EZ)	Cracked at "A" in 20 hr, glass pack degraded at 15 hr.
2	1(N4EZ)	Cracked at "A" & "B" in 50 hr
3	approx 15	Original in N4EZ failed at "A" in 80 hr. Many homebuilders had cracks in less than 50 hr. One stainless system cracked in 12 hr.
4	approx 10	No failures in N4EZ at 100 hr when removed for muffler installation. Homebuilders have had cracks and complete failures at flange in 80hr, 20 hr & 6 hr. One is operating at 130 hr without failure.
5	approx 15	No known failures, however, system may be too short for adequate heat protection of engine valves.
6	1(N4EZ)	High-quality Flight Research Inc muffler-system being developed for Cessna for 150 retrofit. No signs of failure at about 90 hr. Extensive history of durability on Cessna 150.

The most important thing we can tell you about the exhaust system is in the next five sentences. Read and follow them carefully. If a piece of failed exhaust system should drop from the cowl and strike the prop it can fail the prop, cause excessive vibration, and possibly destroy the aircraft. If you are using system #4 or 5 you should immediately (before next flight) install a safety attachment to each tube to retain it in the event it fails at the flange. This can be a small welded tab with several loops of .041 stainless safety wire strung to a bolt or tube on the engine, or a small hole with a loop of 1/6" stainless cable looped over an engine component. This is a definite safety of flight item. Do no risk loss of your aircraft or life due to exhaust tube failure.

We are presently working with Brock to develop a system that we feel has a good chance of solving this problem. It is similar to systems that have good durability in other applications. We will be flying it soon and will keep you posted on the results (see system 7).
SKETCHES OMITTED

Now for the good news. The muffler system built by Flight Research Inc (reported on in "CP" 13, 14, and 15) has recently undergone some internal modifications to reduce its noise level over that listed in "CP" 15. It is now 6 db quieter than their previous muffler (a

reduction of 6 db is a 50% reduction of noise level). Flight Research Inc manufactures the muffler system for the Cessna 152, which had to meet the rigorous, new noise requirement. They are now producing a quiet system for Cessna for replacement on the 0-200-powered Cessna 150's. This is the same system now on N4EZ. It is available now from Flight Research Inc, Airport Hangar 61, Mojave, Calif 93501. This system is complete with muff for carb heat and cabin heat. It is a bolt-on installation on the 0-200, but requires a modification to the cowl, adding "blisters" (see "CP" 14). We built our own blisters by glassing 4 ply BID over a foam bump. We are planning to get tooling prepared so the blisters will be available from Jiran. Thus, the homebuilder cuts holes in his cowl and installs the blisters. All indications are that the Flight Research mufflers will not be susceptible to failures and certainly cannot get to the prop should they do fail. **SKETCHES OMITTED**

VARIEZE PLANS CHANGES

Section I pg 11-7	Foot depressions in back seat should be 1.0, not 1.7 deep to allow room for landing brake, if used.
Section V	Hencolac NUL-V paint is no longer manufactured. Use acrylic lacquer, enamel, or acrylic enamel.
Newsletter 14 pg 8	Dimension missing on exhaust drawing. If radius is too large, pipe will interfere with intake manifold. **SKETCH OMITTED**
Newsletter 13 pg 11	Bill of materials under instrument plumbing -015 should be 0715-015. An315-3(4) should be AN315-3(14)
Section IIA & Section IIC	Ryan Herco fittings in white nylon are different part numbers than the previous polyethylene. Polyethylene Nylon 0715-020 0716-020 Tee 0710-162 0711-162 Elbow 0700-162 0701-162 Adapter
Section IIC page 5	F.S.132.77 should be F.S.133.28
Section I & all "CP"	Wicks Aircraft Supply address should be 410 Pine St, Highland, Il. 62249 (618) 654-7447
Section V	Add "check surface contour as described in "CP" 16.
Section I pg 17-9	Add "do not drill in NG15 - See "CP" 16."
Section I pg 18-3	Add "see "CP" 16 for added tube in Nylaflow fittings on brakes and master cylinders."
Section I pg 3-2	Change 15 in to 13.6 in, change 20-part to 22-part

Section IIa & IIC — Note exhaust system changes in "CP" 16.

SHOPPING - Continental A-75's OSMOH $1900. Kal Nelson Aviation Inc, 9801 Glenoaks Blvd, Sun Valley, Ca 91352 (213) 875-0388.

Aircraft Spruce now has VariEze metal placards with special adhesive for bonding to your fiberglass panel. These are die cut and ready to install. A print of the placards is shown below (not full size). FAA requires full placarding to license your aircraft. **PRINT OMITTED**

Shelf-life of epoxy is two years. Distributors cannot replace epoxy due to settling, etc., if it is approaching shelf-life time.

MIKE & SALLY MELVILL'S VARIVIGGEN

Check the March issue of EAA "Sport Aviation" magazine for an excellent article on November-Two-Seven-Mike-Sally, the Melvill's spectacular VariViggen. This article covers all of Mike's experiences building and flying his Viggen up to December 77, including some great color photos. Note the article has an error - 100 ft/min should be 1000 ft/min. Mike's Viggen is the craftsman's dream in every way, down to the beautiful modern-fighter cockpit layout and upholstery. Since the article was written, Mike and Sally flew to the Sun-N-Fun flyin in Florida and won the runner-up Grand Championship trophy. Their trip totaled over 30 hours including a visit to Key West and flying demos and Mike reported no maintenance was required. Sally is now checked out in the front seat and flew N27MS on their last trip to Columbus.

The adjacent photos show the screen assembly Mike fabricated to protect the prop from any damage due to items loose within the engine compartment.

Mike has prepared the "part two" of the VariViggen construction Manual and is marketing it, himself. This manual has some very valuable information on jigging, skinning, building and trouble shooting the gear retraction system, canopy, firewall, cowling, baffling, exhaust system, SP wing, etc. The manual is $16.00, and is available from Mike and Sally Melvill, Bx 561, Frankton, In 46044, (317) 649-2576. Mike is happy to answer questions you may have about his Viggen or about the construction manual but don't forget to send a self-addressed, stamped envelope for his reply.

Mike redesigned the main gear retraction system to a more complex, but much more durable mechanism. His has been well tested, including over 175 landings on N27MS and has performed flawlessly. He now has available professionally-drawn drawings of his gear retraction system. They are $10.00, from Mike and Sally at the above address. This is a better system than is shown in the VariViggen plans.

JESSE WRIGHT VARIVIGGEN KITS - Jesse now has available a very accurate set of ribs for the vertical fins as well as detailed installation instructions. Viggen builders should contact him for details on canard parts, fuselage bulkheads, inboard ribs, also. His parts are priced

reasonably and can save a great deal of building time. Send 50 cents when asking for info, to pay his printing and mailing cost. J Wright, 7221 S. Colorado Ct., Littleton, Co 80122.

VARIVIGGEN SURVEY - We have no idea how many active builders there are at the present time. We are asking all VariViggen builders to send the following info to RAF. Results of survey will appear in a future "CP".

Name_____S/N_____
Date started construction_____
Currently active building? yes, no.
Chapters of Plans completed_____.
Estimated completion date_____.
Which wing: SP, Standard. Engine type_____.
HP_____.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Special Performance Wing	Gross Weight	1700 lb

PROVEN DESIGN

Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS:

AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow, Box 424, Fullerton, Ca. 92632 (714) 870-7551.
VariViggen spruce kit, plywood kit, hardware, aluminum and fiberglass. Catalog cost $2.

KEN BROCK MANUFACTURING, 11852 Western Ave, Stanton, Ca. 90680 (714) 898-4366.
VariViggen prefabricated components: all machined parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton, Oh 45424.
VariViggen plexiglass canopy.

MONNETT EXPERIMENTAL AIRCRAFT, INC, 955 Grace St, Elgin, Il 60120 (312) 741-2223.
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48706.
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509.
VariViggen welded nose and main landing gear, 1-1/4" sq. steel tube.

MIKE AND SALLY MELVILL

Part Two of Construction Manual
Box 561, Frankton, Ind. 46044

JESSE WRIGHT (VariViggen builder), 7221 S. Colorado Ct, Littleton, CO 80122 (303) 771-5140.
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications

required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

VARIVIGGEN CONSTRUCTION MANUAL Part 1 of a photo-illustrated construction manual, written by Jim Cavis, S/N 31. Includes fuselage, canard, inboard wing, vertical stabs, control system, and landing gear, along with approximately 100 photos. Part 1 also includes helpful sketches on jigs and numerous building tips. The written information is similar to plans chapter 5, except expanded to about 30 pages. Price: $18.50 first class mail, $20.50 airmail overseas.

CP16, Page 12

VARIEZE

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6',5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or

combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance. THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and

induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP AT GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	560 lb
Gross Weight	1050 lb
Range at Max Cruise	700 mi
Range at Econ Cruise	850 mi
Min Speed (full aft stick)	55 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6 square feet
Canard Span/Area	12.5'/13 square feet

SPECS & PERFORMANCE WITH 75-HP CONTINENTAL:

Take Off	1050 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	530 lb
Gross Weight	950 lb

NEWSLETTER SUBSCRIPTION - $4.75 per year
OVERSEAS (AIRMAIL) - $6.50 per year
BACK ISSUES - $1.00 each

If you are building a VariViggen you must have newsletter 1 through 17. If you are building a VariEze from the first edition plans you must have newsletters 10 through 17. If you are building a VariEze from the second edition plans you must have newsletters 16 and 17. Reproduction and redistribution of this newsletter is approved and encouraged.

RAF ACTIVITY since the April newsletter has been hectic. Builder support demands have been high with many new construction projects started and over 20 first flights since April. The excellent safety record has been marred by two fatal accidents which are discussed later in this newsletter. Also, during this time period the plans for the Quickie were completed and shipment of the first Quickie kits has begun. Our new light twin, the "Defiant" made its first flight on June 30.

We have completed additional contract work on the NASA skew wing AD-1 and have run further tests on our solar water heater. So, please excuse the patched-together appearance of this newsletter as it is being crammed together on an extremely tight schedule to get it out before our Oshkosh trip.

Since many of you do not know the size of RAF we are including the adjacent photo. Paul Striplin, on the left, helped us build the Defiant and has now left to pursue his own ultra-light project. Next is Dick Rutan, Burt's brother, who has worked full time at RAF since retiring from the Air Force in April. Dick has extensive flying experience both in general aviation and military fighters. He also holds an A&P license. He now owns the VariEze prototype, N7EZ, and is in the process of removing its Volkswagen engine and installing a Franklin 60-hp which he plans to use to make some record flights. Next are Burt and Carolyn Rutan, founders and owners of RAF. On the far right is Marge Merrill, with us since April. **PHOTO OMITTED**

DID YOU KNOW? Ferde Grofe's film "Flying is VariEze," has won the Aviation Space Writers Association's Award for Visual Communication. See "CP" 13 if you want a copy of this film.

The VariEze plans (Section 1) are now available in the second edition, with all revisions from the first two years incorporated. The Section I education chapter is extensively modified, incorporating all the new methods now recommended. Due to the large amount of builder support

and inflation we have raised the price of Section I. Prices for all other items are the same (see attached flyer). This is our first price increase since we started business in 1973. We plan to have Section IIA and the VariViggen plans updated to a second edition soon.

The AD-1, designed at RAF and being built by Ames Industrial Corp, N.Y., is 70% finished and should be delivered to NASA late this year. The adjacent photo shows the aircraft. It is about the same diameter as an EZ, but is over 35 ft long. Its entire structure is basically similar to a VariEze.

The VariEze is approved for construction in Australia, but is being held up in Canada due to a wing-loading restriction.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Mike & Sally's Viggen with N4EZ.

AD-1 skew wing aircraft.

The adjacent photo shows the largest gathering of VariEzes in the world. At a surprise birthday party (35th) for Burt given by Carolyn, all nine showed up at Mojave in June. Attending the EZ's were Don Shupe, John and Wilma Melville, Ed and Jo Hamlin, Jim Heitkotter, Les Faus, Hal Reynolds, Ernie Taylor, and Dick Rutan. The party was attended by over 80 people!

CP17, Page 1

The VariEze/VariViggen survey results ("CP" 16) have not yet been completed since only about 10% of those flying have supplied the data. Those of you that are flying, please send in what info you have even if it is incomplete, so we can get it complied and printed in the next "CP".

Based on information received at RAF there are about 65 VariEzes that have flown. About 90% of them are currently in active flying status. Several have been damaged in minor accidents, have been repaired and are back flying. Two have been damaged beyond repair.

We have just completed a photo session with noted "National Geographic" photographer, James A. Sugar. The photos are intended for an article to be published next year on the subject "Advances in Aviation." Mr. Sugar, who is well known for his special effects set up some spectacular shots including one with a wide-angle remote camera mounted on the nose of the Defiant looking aft. This shot was done at dusk, with colored strobe lights illuminating the inside of the cockpit and included the VariEze in close formation behind. "National Geographic" always does first-class photography, so we are certainly looking forward to seeing the article.

QUICKIE - The Quickie program is off and running! The initial kit deliveries began in early July. Current backlog on kits is approximately 2 to 3 weeks. The prototype, N77Q now has over 125 hours flying time. Tom and Gene plan to fly it to Oshkosh on the 25th or

26th of July, so if you live along Route 66, look up! The Quickie has received some excellent coverage in the aviation press, including "Flying" (color coverage in June issue), "Air Progress", "Plane and Pilot" and various others. Peter Garrison, well known to "tell it like it is", had this to say in the "Flying" article after his flights in N77Q. "The beauty of the stalling characteristics (which are shared by the VariEze) is that you get perfectly clear, perceptible stall warning without any loss of control or much loss of performance. At sea level with the stick full back and with full throttle, the Quickie will actually climb, bucking, at 150 fpm.* A high effective aspect ratio further assures that there will be little loss of climb performance in turns; so in the Quickie, you can maneuver with perfect confidence at minimum speed, all the while climbing, treating the stall regime just as you would any other portion of the flight envelope."

"The upswing in my confidence is remarkable. Suddenly I can't resist the temptation to keel over past 90 degrees and dive toward the little figures beside the runway. With the throttle back at idle, the airplane suddenly feels silken. It's delightful to fly. On the deck at almost 110 knots, I sail past the spectators, then pull sharply, watching the airspeed; it bleeds off slowly. Near the end of the zoom, I drop a wing, turn 90 degrees and level out in gentle bucking, then pick up a few miles an hour, keel over again and swoop down for another pass. The knowledge that this airplane can't run out of airspeed does wonders for my enjoyment, and I realize that unconsciously I am adjusting my climbs and descents to conserve potential energy, in the same way that glider pilots unconsciously adjust speed and course to capitalize on small upward air movements. Despite the scanty surplus of power, I am able to work up and down a block of air nearly 1,000 feet deep without devoting much time to scrambling for height. The combination of its fine, effortless, intuitive handling qualities, clean design and perfect immunity to low-speed mishandling makes it fantastically enjoyable to fly. It's a toy, but one of those high-grade toys that work sublimely well. Its long suit is gadding about on weekends, airport-hopping, dog-fighting or racing over the wilderness, belly to the ground, leaving no mark behind. It's cheap, it's easy, it's safe, and, best of all, it's a good airplane, a pilot's airplane and really a joy to fly." Peter Lert's "Air Progress" article had quite bit to say about stall characteristics: "Like the VariEze and Burt's earlier Vari-Viggen, the Quickie can't be stalled; the wing loading and airfoil of the canard are chosen such that it invariably stalls before the aft wing, and hence cannot pull it up to a stalling angle of attack. Thus, the "stall" consists of the canard stalling, then dropping until a knot or so of speed is gained, then stalling again, and so forth; to the pilot, this appears as a pitch oscillation of perhaps 15 degrees at the most. In the VariEze, I'd call it "nodding"; since the Quickie is so short-coupled, the motion is a bit faster, and I'd call it "bucking." After the first couple of cycles, during which it increases in intensity, it remains steady; about like running an outboard skiff over 6-inch chop at about 10 mph. This is with the stick held fully aft against the stop, mind you, and at full power in this condition the Quickie won't nose up to the vertical and roll over--it can't. It just sits there and bucks, climbing at maybe 160*fpm. Roll it into a turn (since the aft wing never stalls, the ailerons are still effective) and it just bucks its way around the turn. I was, and am, impressed--this may just be the safest plane I've ever flown, at least as far as low-speed flying qualities are

concerned." The Quickie is probably the easiest single place aircraft for a low time pilot to transition to. Its pilot demands are small and its flying qualities are honest in every way. One pilot with flying experience ranging to military jet fighters commented that the Quickie was the most fun airplane he had ever flown. For further info on the Quickie, or for their excellent $6.00 info package contact Tom or Gene at Quickie Hangar 68 Airport, Mojave, California 93501 (805) 824-4313.

*Later data show this to be 300+fpm at sea level.

CAN I BUILD A COMPOSITE AIRPLANE? WILL I ENJOY WORKING WITH GLASS & FOAM? IS MY WORKMANSHIP ADEQUATE TO BUILD AN AIRPLANE? WHAT ARE THE TECHNIQUES USED IN VARIEZE & QUICKIE CONSTRUCTION?

There is now available an introductory kit to answer these questions for you. The kit consists of a book and sample materials, or the book can be purchased separately. The book, "Moldless Composite Sandwich Homebuilt Aircraft Construction" consists of 26, 11x17 pages (equal to 52 pages) describing how the material is applied, education on the materials, tools required, inspection and repair methods. The bulk of the book is the new second edition education chapter from section I. Sample materials include: foam, fiberglass (2 types), epoxy, microspheres, flox, peel ply, wire for hotwire saw, etc. The book is $14.50, and is available from Aircraft Spruce, Wicks Aircraft Supply, and Rutan Aircraft. (Add state tax, if resident). The kit (book and materials) is $45.50, and is available from Aircraft Spruce and Wicks, not from Rutan Aircraft. (Add state tax, if resident).

DEFIANT PHOTOS OMITTED

DEFIANT - Our new light twin made its first flight on June 30, 1978, with Burt at the controls. Within one week Burt and Dick had logged enough flying for FAA to remove its area restriction and had obtained all basic performance verifications. The only maintenance or adjustments required has been changing the stiffness of the nosegear steering pushrod. This has been the cleanest initial test program we have seen on any type aircraft.

Curtis Barry, Port Jervis, N.J. won the "Name-the-Plane" contest. He added that defiant infers, "the aircraft defies all the common assumptions about current production twin engine aircraft - in pilot skill required, safety, performance, construction, and handling." We waited until after the aircraft had flown to name it, as we wanted to be sure it did indeed meet the above definition. As those of you that have recently visited know, we are extremely excited around here, since we are finding that Defiant actually is exceeding the estimated performance estimates and is verifying the no-procedure-for-engine failure design goal. It doesn't take a lot of study to realize the impact on flight safety of a twin that not only has no appreciable trim change at engine failure, but requires no pilot action when it does fail. You can fail an engine at rotation for takeoff or during a go-around in the landing flare. The pilot does nothing, he climbs out as if nothing happened. He has no prop controls to identify and feather.

He has no cowl flaps to open, no wing flaps to raise, no min control speed to monitor (he can climb better than the other light twins even if he slows to the stall speed), no retrimming is required, he can even leave the gear down with only a 50 fpm climb penalty. The only single engine procedures are the long term ones: (1) cross feed if you want to use all fuel on operative engine, (2) magnetos off. Note that, in general, you do not lose the alternator or vacuum pump on the failed engine since the engine windmills at 1000 rpm (fixed pitch prop). Why no cowl flaps? The two updraft cooling systems were designed to have large positive cooling pressure increases with power and angle of attack. When you are cruising the cylinder head temps stabilize at 370 degrees F. If you then fail an engine and execute a full power climb and slow to best single-engine climb speed the full-power engine will cool to 350 degrees F with no pilot action (same mixture). The engine installations are simpler than the most simple single. Baffling is less complex, blast tubes for mags or ram air plumbing for carb and carb heat are not required. There are no oil coolers. Oil temps run to 200 degrees F during a climb to 15,000 ft and stabilize at 190 degrees F at high cruise at outside air temperatures of 40 deg above standard conditions!

The most surprising good news is that the Defiant does not have the annoying, loud out-of-sync noise common to the Skymaster. The pilot has to split the throttles considerably to detect out of sync at high power, and at low or medium power the sync noise is not detectable. The sync noise is more objectionable on other twins than Defiant, even though they use constant speed props mounted on wings. We feel the main reason is the high damping of the Kevlar/wood props and composite structure. Using Flight Research mufflers, the Defiant makes less perceived noise for a ground observer than the average medium performance single.

The airplane is a stable IFR platform, with less trim changes than conventional twins. It has a very solid "big airplane" feel. Approach speed is 75 kt at light weight and 85 kt at gross. We are withholding detailed performance data until it is completely generalized and presented for all weights, but the following is typical of that being obtained: Cruise at 65% power (maximum cruise) at 12,000 ft is 188 kt (216 mph) without wheel pants. Single engine climb gradient (ft increase per mile) is almost twice that of the new light-light twins at any given loading condition. Single engine service ceiling is well above these aircraft even with the gear down and the airspeed 15 knots off the best climb speed, and this is obtained instantly, not after a clean up procedure! We gave Joe Tymczyszyn, FAA test pilot from the Los Angeles AEDO a ride that included single engine go-arounds initiated in the landing flare. His comments "unbelievable, single engine procedures are refreshingly simple."

The Defiant is big inside - 2 inches wider elbow room, 8 inches longer cabin, 6 inches more knee room in back seat and 3 cubic ft more baggage volume than the Beech Dutchess. To get to gross weight in Defiant you can top the tanks for 1100 NM range, add four 175-lb adults and add 75-lb baggage to an IFR-equipped airplane.

We will continue to keep you informed about the Defiant through this newsletter and other magazines. Please do not ask about further information at this time. We have no plans to market Defiant at this

time. It is merely a proof-of-concept prototype for aerodynamic research.

CP17, Page 3

VARIEZE'S FLIGHT RESEARCH MUFFLER SYSTEM - We have received the first VariEze owners' comments on the new muffler system ("CP" 16) - Lee Herron's comments follow: "Mufflers arrived Thursday evening, built the blisters on cowl Friday evening and Saturday and flew to two fly-ins on Sunday. Technically they look great and blowing the exhaust inboard at the fuselage boundary layer then through the low speed area of the prop is brilliant! As for noise, it is much quieter but now the cabin air intake (vent) makes too much noise - any ideas? As for speed about 4-5 mph penalty. Heat buildup around mufflers was a problem on the 1st test flight, but we cut outlets in the rear of each blister (see photo) and it cured the problem - cylinder head temp was not affected by mufflers. The small bump on the left blister is to clear the carb heat hose - carb heat is 15 degrees better now." Note that Lee carefully sealed around the exhaust pipe outlet. On N4EZ we left about 0.3" gap around the pipe to allow excess heat to escape and we don't need the outlets.

Additional comments on the F.R. mufflers: Do not omit the support on the front of the right muffler. This is a piece of 3/8x.035 steel tube flattened on each end. It bolts to the tab on the muffler and to an accessory case stud on the engine as shown. If you want to use cabin heat you can plumb it as shown. **SKETCHES AND PHOTO OMITTED**

VARIEZE FUEL SYSTEM - We have had reports from several builders indicating that the fuel valve has become stiff and hard to turn in service. One builder solved this by lapping the valve with valve-grinding compound and substituting a lighter spring for the one in the valve. If your valve is hard to turn (over 5-lb force at handle) fix it before you fly. One builder had to make a forced landing because the valve was so stiff that it was not completely in the "wings" position when selected. If it is only 20 degrees toward the "fuselage" position it will drain the fuselage fuel into the wings! Thus, when he selected fuselage for the descent after nearly depleting the wings, he ran out of gas since the fuselage tank was empty. Also, note that the rivet that attaches the valve to the universal should be changed to a #8 screw so the valve can be easily removed.

One EZ owner stuffed baggage into the compartment behind the seat in such a way to pinch off the fuel lines and restrict fuel flow - be careful about this.

COMPOSITE CONSTRUCTION
A problem area has been discovered recently that is very important and should receive the utmost attention of everyone building foam and glass. Nat Puffer noticed a debond bubble on his wing after the aircraft had been painted. A similar debond was noticed on the Quickie vertical tail (a debond is where the glass lay up detaches from the foam, a delamination is where individual layers of glass cloth detaches from each other). Nat and RAF traced the problem to the following: the debond occurred in areas where the glass lay up was slightly dry, ie.

where pin holes from the surface can reach down to the blue foam. Nat wiped his wing down with solvent before applying the primer. The solvent and traces of the primer reached the foam surface and locally dissolved it. Note that this occurs only with the blue foam, not PVC or urethane. These debonds were easily repaired by drilling holes at opposite ends of the debond area and injecting epoxy in one hole until it came out the other, then weighting down the bubble during cure.

Because of this possibility we are insisting that you: (1) Never wipe down wings, canard, vertical fins, or control surfaces with any type solvent. (2) Before applying materials that can attack blue foam (featherfill, primer, etc.) inspect carefully for dry areas and fill them by wiping on epoxy (RAEF), then sanding dull after cure. (3) Inspect your critical structural areas ("CP" 15, pg 5) for debond by tapping the surface with a 25 cents coin - a debond will be indicated by a "dull thud" rather than a sharp "knock" when the coin is lightly struck on the surface. This can (and must) be done on both a finished or in-construction aircraft.

Shelf Life - Epoxy which has exceeded its two year shelf life should not be used in any critical aircraft parts regardless of its apparent acceptability. This is always the case in aircraft manufacturing and of course should be followed by the homebuilder.

Workmanship - Always question yours and others' quality of construction. Remember, the quality control criteria represents absolutely minimum acceptable quality - yours should be much better on the average. Never accept voids where complete surfaces should contact. Be sure to get complete squeeze out of bonding materials. If you see someone doing marginal or unacceptable work, suggest that he review all the QC requirements, chapter 3 material and all hints in newsletters. Then he should build a noncritical part and inspect it. If it does not look good he should consider not completing his airplane. The only thing worse than no airplane is an unsound airplane.

Peel Strength - We have received several comments on how easy it is to delaminate fiberglass plies after they begin to peel. Large difference between tensile and peel strength is one of the primary factors that determine the ply configuration during design. The following values are averages and you can test for them if you wish to check your workmanship. A 1-inch wide strip of UND has a tensile strength of about 660 lb. If it is peeled up from a surface it will peel off with a 20-lb pull at 45 degrees from the surface and only 7 lb if the strip is pulled at 90 degrees (straight up from the surface).

VariEze Main Gear Torsion Stability - Les Faus had a strange thing happen to his main gear. While his airplane was sitting in the hangar on a hot day his gear twisted to an exaggerated toe-in angle on one side. This should not have occurred, as it is believed the temperature did not exceed 130 deg F. His gear was removed and placed in Jiran's oven where it promptly returned to its correct shape. We suspected the

primary cause to be that Les had not installed the 45-deg BID wrap on the strut ("CP" 13 and 15). The BID wrap stabilizes the strut in torsion if the epoxy should soften at high temperature. To verify this we built the rig shown in the photo. It is a VariEze gear with an unwrapped strut on one side and a wrap (per "CP" 15 using RAEF) on the other side. It is loaded to simulate the torsion of a parked airplane, full of gas. The struts are painted black so their temperature stabilizes at 140+ deg in our desert sun.

While we were unable to obtain the exaggerated twist of the Faus gear we did verify that the BID wrap must be used. After one week of exposure the wrapped gear had a sag of 0.3 inch. The unwrapped side sagged as much as one inch then returned (still loaded) to about 0.8 inch. Be sure you have correctly installed your wrap. If you have fibers at 90 degrees instead of 45 degrees, for example, there is no torsional support. If you have noticed excessive tire wear, check your toe-in - it can have long term creep if the BID wrap is not installed properly. This has not occurred on N4EZ even though it is continuously parked either outside or in a non-cooled hangar with outside temperatures as high as 115 degrees F (46 degrees C). N4EZ has never required toe-in adjustment. It averages 80 to 100 landings on a set of the 4-ply tires. If your gear appears to have BID on it as received from Jiran this is only a cosmetic repair of mold surface voids, not the required homebuilder-installed wrap. **PHOTO OMITTED**

BUILDING HINTS
A carpenter's square is handy for checking gear toe-in; hold one leg on the axle and sight down the other leg to a target in front of the airplane. Be sure CS12 arms are lined up to sight into the pivot holes of all CS2's. CS12 may have to be rotated to line up all pivot holes (pg 5-4 of Section I).

We have noted some inaccuracies in the Westline tachs (RPM indicators). The best way we have found to check them is to build a low-cost Heath kit "Thumb Tach" model GD#69. This little hand-held box will indicate RPM by pointing it at a propeller, measuring the frequency of sunlight reflected from the blades. It even works well from the back seat of an EZ in flight. It is accurately calibrated by pointing it at a light bulb (60 cycles/sec).

When finishing glass in preparation for featherfill, use coarse 36-grit paper, since featherfill requires a mechanical bond, not a chemical bond. Do use the 25% micro in the featherfill. We finished the Defiant twin with featherfill, 70S primer lacquer putty for pin holes then painted with Dupont Centari white acrylic enamel. We had excellent results. The Defiant has 2-3 times the surface area of an EZ. We used 4 gal featherfill, 5 gal of 70S, and 1-1/2 gal of Centari. Total finishing weight growth was 18 lb.

It is acceptable to use soapy water if required to check for fuel tank leaks (repair per "CP" 14, pg 10). If you do, be sure to rinse the area well with clean water and allow it to thoroughly dry before applying epoxy or primer.

Be sure to check the thickness variation of your brake discs before you taxi, particularly if you have an early Rosenhan set. Uneven discs or unbalanced wheels can cause main gear vibration.

EPOXY SENSITIVITY - The U.S. Department of Health, Education and Welfare has a booklet on practices for fiberglass lay up - HEW publication (N10SH) 76 - 158; contact HEW, 4676 Columbia Parkway, Cincinnati, Oh 45226

VARIEZE PITCH CONTROL SENSITIVITY - The VariEze pitch control system was intentionally designed for lighter control forces than a conventional aircraft. The reason for this is that a side arm control is used, whereby the pilot rests his arm on the side console and uses only his wrist muscles to fly the stick. The lower control forces (higher sensitivity) have nothing to do with the aircraft being a canard configuration. We have found that in a large percent of cases (at least half) that this has not been desirable for transition of pilots who have never flown a sidestick. Most pilots on their first flight in the VariEze make the takeoff with a hard grasp of the stick and use their biceps to fly, much like they would in a Cub or Cessna. In this configuration the airplane feels overly sensitive and is difficult to fly smoothly. While we know of no accidents caused by this it is not unusual to see a VariEze bob up and down during its first few seconds of flight with a new pilot. Using some hindsight, which is always more accurate than foresight, we have concluded that in general it would be better to have much stiffer controls in VariEzes, with more stick force required to change attitude (less sensitive). Within the last two months we have tested a wide chord elevator on N4EZ and on two other VariEzes. This modification moves the center of pressure of the elevator further away from the pivot and results in the stick forces being nearly double their original value. This does not make the controls overly heavy, merely more solid. We like the new elevator enough that we have made it standard on the 2nd edition of the VariEze plans. This is not a mandatory change for those of you flying, since most of you have adjusted to using the wrist for control and most of you like the light responsive control feel. However, many of you do feel that the elevator is a lot lighter than the ailerons and will like the better harmony provided by the wide-chord elevator. We do recommend that you extend the chord on any airplane that has not yet flown unless the pilot is confident that his proficiency in sensitive aircraft is good. The new elevator cross-section is shown, full size in this newsletter, along with a foam template to be used in original construction. Note that to retrofit you can merely add material to your completed elevator. This can be styrofoam with one ply BID @ 45 degrees on each side, lapping onto the original skin, or you can bond on balsa wood, carve to shape and cover with a light dacron or glass cloth. Use the templates to carefully check the shape of your elevator. Any variance in the shape can effect the trim capability of your airplane. For example one airplane, N37EZ had an elevator in which the bottom was kinked, as shown, not flat. This airplane exhibited a very strong climb tendency and had to be flown with a firm forward stick force to fly level. This airplane was extremely hard to fly and was overly sensitive. Now, after the elevator was extended to the new shape this airplane has excellent pitch stability and flies very solid.

Note that the new wide chord elevator is reflexed up at the trailing edge with the bottom flat. This is required so that the trim system has enough authority to trim hands-off at low speeds. Check Your

Elevators. If they do not have the correct cross section, your aircraft will be difficult or even dangerous to fly.

VARIVIGGEN ACCIDENT

The following report was written by Mike Melville who flew his VariViggen up to aid in the FAA investigation of this tragedy.

On 21 May 1978, Harold Reiss lost his life when his VariViggen N29HR crashed 1/4 mile off the end of runway 10 at Illini Airport, Indiana.

Burt called and asked if I would go to the crash site and assist the FAA in their investigation. I agreed and was on scene by noon the next day.

Along with the two FAA investigators we determined that there was no mechanical problem with the aircraft.

Flight and engine controls were attached and functional. There was fuel in the lines, the engine had good compression on all 4 cylinders and the mags were operational. The engine was running on impact as evidenced by prop blade failure due to powered rotation. The aircraft hit the ground 60 degrees nose down and 100 degrees angle of left bank. The canard hit first, followed by the left wing and nose. The canard came off in one piece and the fuselage failed at bulk head F20 and F32. The left wing failed down due to the 100 degrees bank angle. The S.P. wing outboard sections failed from foam crush and skin splitting at the leading and trailing edge. The outboard stub spar did not fail. The engine and mount was undamaged but the mount did push the F152 bulkhead about 12" forward but did not enter the passenger compartment.

Lack of any impact damage to the front canopy locks and outward failure of the canopy open retainer cable indicated the canopy was open on impact.

At the moment of impact Harold was struggling to close the canopy and still had his hand on the canopy bow after impact.

The FAA findings were that Harold took off with the canopy closed but not locked and at 300-400 ft alt on takeoff the canopy blew open.

Eye witnesses reported the aircraft pitched up and down rolled left and right before rolling left and pitching down into the ground.

The conclusion was that Harold became more concerned with the open canopy than aircraft control and crashed. He probably thought the canopy would come off and go through the prop. In actuality the canopy would not have come off and even when open would not have caused any unmanageable flight control problems. An old Air Force adage is certainly applicable in this situation:

---TO HANDLE ANY EMERGENCY---

(1) Maintain aircraft control.
(2) Analyze the situation.
(3) Take proper action.

NOTE THAT NUMBER ONE PRIORITY IS AIRCRAFT CONTROL.

On one occasion each, both Mike Melvill and Burt Rutan forgot to lock the Viggen canopy for takeoff. Mike's opened at 300 ft on climb and he was able to catch, close, and lock it inflight while maintaining control. Burt's opened during takeoff roll. He closed, locked it, and continued the takeoff. Do not assume it will not happen to you. If you are flying a Viggen or a VariEze, ground your airplane until you install the secondary catch.

Since both VariEze and VariViggen aircraft are both susceptible to the pilot taking off with the canopy unlocked we are asking all VariEze and VariViggen owners to install the secondary safety catch shown in CP15 pg 8. We consider this modification a mandatory safety change and ask your help to insure that all VariEze and VariViggen, are grounded until this safety catch is installed. The one we installed in N4EZ is simpler than the CP 15 design and is more positive - see below. Note that the safety catch will prevent the canopy from opening more than one inch even if the pilot forgets to lock it. To open the canopy normally, raise it one inch, push in on the catch then open. This works the same as the secondary catch on a car's hood. **SKETCHES OMITTED**

CP17, Page 6

VARIEZE ACCIDENT
On 3 July 1978, Jim Boyd was fatally injured in the crash of his VariEze about 18 miles south of his takeoff point (Klamath Falls, Oregon Airport). Dick flew up to Klamath to help with the investigation. The following is capsulization of what he found:

a. The aircraft impacted in a steep left bank (35 degrees plus) at least 20 degrees nose down at a high rate of speed. There was extensive damage to the left wing, canard and fuselage forward of the main center bulk head. All aircraft components were located at the crash site thus no in flight structural failure was indicated.

b. Observers thought that Jim was only going to make a high speed taxi test. Tower personnel reported he made one smooth and normal runway flight and landing then reversed direction, took off and departed the traffic pattern. Jim reported "he was indicating 145 MPH and going to the south practice area". The weather was 1500 overcast, good visibility at the airport but lower ceilings to the south with rain showers. One controller thought he saw Jim fly into a cloud. Local people living near the crash site said the weather was "bad" that morning. But exactly how bad could not be precisely determined. There was heavy rain on the wreckage between the time of the crash and when it was discovered some 5 hours later. No one observed the crash.

c. Jim had done an outstanding job of building the aircraft. Excellent workmanship was evident throughout. Even the interior of the cockpit was sculptured and finished with feather fill to a high gloss.

He had a VOR receiver, VHF com radio, transponder and a stereo cassette tape player. With that finish, a Continental 0-200 engine with alternator and a 25 lb battery the aircraft was considerably over weight. ???? lbs empty) other than the weight there were no builder discrepancies noted.

d. The prop was virtually undamaged. However, nothing could be found to indicate that engine could not produce power. Good compression, both mags normal, fuel on, filters clean, carb float bowl full of clean fuel. One reason for no power at impact could have been the key type mag switch was OFF and the key was out and found 20 feet away from the cockpit, indicating that the pilot had shut the engine down before the crash by removing the key.

e. Jim's friends including Larry Burton, the local EAA Designee, had all advised Jim to get someone more experienced or get more recent experience himself, before he flew his aircraft on its first flight. Jim was a commercial pilot with an instrument rating 200 hours total time, but he had not flown in the past two years except for a one hour biennial flight review the day before in a Cherokee 140. Jim had never flown an aircraft with a stick.

f. Jim's wife said he was very anxious, uptight and on kind of an ego trip that if "I built it, I can fly it". She said she tried to talk him out of flying it, "but you can only tell a husband so much". If it can be determined that the prop was stopped at impact, then it indicates that the aircraft at some time before impact was traveling at less than 60 knots and had the switch off or a fuel interruption. VariEzes windmill at speeds above 60 knots with fuel off or ignition off. Once the prop stops (below 60 kts) you then have to speed to above 120 knots to start windmilling again. This points to speculation that he was disoriented in clouds, since it would be highly unlikely that he was practicing stalls to below 60 Kts on a first flight with a low ceiling, particularly with ignition or fuel off.

FLIGHT TESTING - We continue to see examples of homebuilders not following recommended procedures in their flight testing. We cannot emphasize enough that the information in the owner's manual and newsletters is based on actual experience with our aircraft and that of other homebuilders. Do not expect success unless you follow all the recommended procedures! We are summarizing a checklist below of some items from previous newsletters. Be sure to follow all of them.

CHECKLIST FOR INITIAL
VARIEZE FLIGHT TESTING

1. Follow Appendix I of 2nd edition Owners Manual to the letter for inspection and weight/balance.

2. Check that canard is trimmed to 142" unless limited by fwd cg ("CP" 14).

3. Check elevator dimensions and contour of canard and elevator ("CP" 16 & 17). Wide chord elevator is recommended.

4. Canopy latches, seals and locks must be secure. Hood latch (page 6) must be installed.

5. Fuel system - valve must work smooth & positive. Use full fuselage tank and 6 gal per wing for first flight.

6. Weight must be below 900 lb gross. Cg should be in the forward part of the first flight box for first flight ("CP" 14 & 13).

7. Remove all equipment not absolutely required for flight, to get weight as light as possible. Do not fly first flight with a starter or alternator - These are double-penalty items, requiring nose ballast to get to the fwd cg for first flight ("CP" 13 & 14).

8. Airport must be smooth surface, runway length at least 6000-ft to allow runway flight. 4500-ft at sea level is absolutely minimal (Owners manual).

9. Pilot proficiency - current and comfortable in at least two different types - one should be high performance. Runway flights in two types made before conducting tests ("CP" 12 & owners manual). Note..., that the VariEze is a high performance aircraft and is "hotter" on takeoff and landing speeds than the slow training type aircraft. Do not try to learn proficiency at the same time as you are making flight tests on a new airplane. "Learning to fly in a VariEze is like learning to drive in a race car or learning to ride on a competition dirt bike." Study the owners manual before beginning tests.

10. Weather - See owners manual. Ceilings should allow glide to the airport during the entire first 25 hours of testing, preferably first 50 hours.

11. Stay in the traffic pattern or in radio/visual contact with your ground crew or be sure to have a chase if you depart the airport traffic area. Flight testing is not something to be done alone.

12. Check your mental state; be sure you are calm and can think straight. Ask someone else to evaluate your state of mind. Be sure your "ego" doesn't get in the way of good judgement. If all is not well fix it first, then fly (mechanical or mental). Above all don't let a big crowd, TV/news reporters pressure you into anything dumb. Best to have no spectators, just minimum necessary ground crew.

13. Wear a parachute and be at least 8000 ft AGL when expanding your high speed envelope above 160 mph or when expanding your low speed envelope below 70 mph.

VARIEZE PLANS CHANGES - Incorporate these NOW

Owners Manual Appendix I	Add "check freedom of fuel valve. If it requires more than 5-lb force at handle the valve must be overhauled. CAUTION - if valve is selected between wings and fuselage position, the fuselage tank will drain into the wings."
Newsletter II	Substitute a AN 525-832-12 screw and a AN

pg 6 & Section IIC pg 8	364-832 nut for the rivet that attaches the universal to the valve. This allows easy removal of the valve.
Section I Chapter 22	Add: The hood-catch shown on page 6 of this newsletter is mandatory and must be installed before flight. This protects the pilot should he takeoff without locking the canopy. Do not omit.
Section I pg 17-9	Refer to the two AN3-11A bolts on NG11. The aft bolt should be installed with the head on the bottom to definitely avoid it interfering with the NG14 spacer when the gear is locked down check for positive clearance in the down position. Grind material from NG14 if necessary to provide clearance. We have determined that this interference, (which prevents NG11 from reaching its full locked position) is the cause for the inadvertent nose gear retractions during taxi that were reported in previous newsletters. Confirm this clearance, even if you have had no trouble with yours.
Owners manual pg 30	Add "torque prop bolts 180 inch-pounds"
Section I Chap 5 (1st edition only)	Add "refer to CP17 for the recommended (not mandatory) wide chord elevator."

BUILDERS CLUBS - Bob Zahner, 906 Millard, Tallahasse, Fla. 32301 is organizing a VariEze builders club for Florida and South Georgia - contact him directly.

QUESTIONS/ANSWERS

Q. I see that when you shut the engine down on the 0-200 Continental VariEze that the prop stops windmilling if you slow to below 60 knots and stays stopped until you increase speed above 120 knots. Is this true of the Lycoming too?
A. Probably not, since the compression is more. Ken Swain has the extra high-compression 0-235-FZB in his EZ and reported that when he stopped his he had to go to nearly red line speed to restart. We suspect that the 0-235 C will windmill down to about 70 knots and will restart at about 150 knots.

Q. Do you advise doing the speed brake depression when carving the fuselage in chapter 12?
A. No. This is best done later, exactly as shown in Section VI.

Q. I'm now using the CP16 pg 9 method to jig the winglets to the wing. I've noted that this method results in the top of the winglet being further inboard than the plumb bob method. Is this intentional?
A. Yes. We failed to mention that in CP16, but we did intend to remove some of the 'cant' to reduce dihedral effect. The EZ is less susceptible to wing rock at low speeds and is a bit easier to fly with

rudders with some dihedral effect. The Defiant's winglets cant inward from vertical about 3 inches. Some builders have found some mis-match of the winglet incidence template at the trailing edge and rudder hinge line. This is of no concern since the incidence template is not needed when using the CP16 method.

Q. Good to see that the new CP16 method of attaching the NG15 to the strut has eliminated the holes thru NG1 giving it full strength. My problem is I have already drilled the two holes thru NG1. Do I have to buy a new strut?
A. No. If you remove NG15 and shorten the strut about 3/4-inch you can reinstall it exactly per CP16 and obtain essentially full strength, since the old hole will be well within the socket. This makes the aircraft sit 0.5 degrees lower during taxi (no problem). Remember, the new method eliminates all holes thru the strut at the lower end. The strut is no longer the weak point in the nose gear. The fork or NG10 will now fail before the glass strut.

Q. I am considering adding a few extra plies of glass in a few areas to beef them up for extra strength is this OK?
A. No! More than likely the extra material will not be added where first failure will occur anyway. The extra weight in most places will actually weaken your airplane in that its maximum 'g' capability will be less and failure on hard landings will be more likely. The best thing you can do for optimum safety is to do perfect workmanship with the exact ply arrangement in the plans. Also, stiffer structure can change flutter modes.

Q. I am having trouble getting a smooth hole drilled in fiberglass on diameters over 1/4", any suggestions?
A. Yes. A piloted spot-face, countersink, or counterbore bit works excellent. In fact this should be considered a must on the 1/2" holes in the landing gear tabs. These are very difficult to do adequately with a drill bit.

Q. I want to find out exactly how much the VariEze materials and prefab parts cost, and how much optional prefab parts are available. How do I find this? A. Refer to the flyer in this newsletter. Contact each distributor and obtain his catalog for price and availability. Its generally best to study the plans carefully to decide if you want to build or buy the prefab parts. If you build most of them yourself you can save a great deal.

SHOPPING - Aircraft Spruce & Wicks report that all VariEze materials are readily available with no major backlogs. They have the Composite Introductory Kits in stock for immediate delivery.

Ken Brock - no major backlogs; plenty of new 3-inch prop extensions and face plates for wood props are in stock. Be sure you are using the correct face plate for your wood prop. Minimum thickness is 1/4" to avoid local crushing. Ken also has NG25 and NG26 in stock now.

Jiran - all items now being shipped well within the 8-week backlog. Fred reports that the prefab VariEze wings and center spar should be into static test within 3 weeks with flight tests to follow. These may be available in Kevlar, to save weight. Jiran also reports that he has produced a prototype vacuum - bagged Kevlar cowl for the VariEze. These

will be expensive, but at a 10 lb savings it may be justified for you guys with the big heavy engines.

Canopies - we finally have a solution for those who have been complaining about how expensive it is to get a canopy out to the east coast. Walt Hoy of The Airplane Factory, 7111 A Brantvista Ave., Dayton, Ohio 45424 (513) 845-9872 or (513) 233-7754, who has been building VariViggen canopies for the last 2 years is now producing an excellent VariEze canopy. Compared to the original, it has a bit more forward-cockpit head room and visibility. Walt also offers a 1/2-price replacement for any breakage within the first two years. Send Walt a self-addressed, stamped envelope for his flyer on the EZ canopy. We have a Hoy canopy here at RAF if you want to inspect it. Cowley has notified us that he is phasing out the canopy production, but will still have some available for the next 2 or 3 months.

CP17, Page 8

VARIEZE HINT FROM NAT PUFFER:

"If you wish to get a tight seal where the exhaust pipes exit the cowling, and still be able to remove the cowling easily, especially if you curve the exhaust pipes aft as I did - make a gasket plate that stays with the exhaust pipes where you remove cowling. It takes only a few flat headed screws and nut plates to hold the gasket plate to the cowling when assembled. Rivet assembly together on exhaust pipes.

This is a custom fitting job, but it gives tight seal, makes cowling removal easy, and allows more freedom in configuring pipes to individual taste. Also it relieves bending forces on cantilever pipes; especially if you do this, as I did on the right side. **SKETCHES OMITTED**

VARIVIGGEN - Mike and Sally Melvill have really been giving their Viggen a workout. They visited RAF in May during a 6000-mile trip (see photo on cover). Mike and Sally were alternating front/back seat pilot chores. They were loaded down with baggage and handled a 9000-foot density altitude takeoff at Albuquerque with no problem. His summary after arriving home "once again the Viggen has proved to us what a really practical cross-country machine it is. We love it and would not trade it for anything".

Mike designed and built a very clever angle of attack instrument for his Viggen. Instead of a potentiometer on the vane (the one that's so hard to find) he made up a wiper with 3 electrical contacts. These go to 3 lights on the visor arranged in a vertical format. When the center light is on (green) the airplane is "on speed". When the top light is on you are too slow, too fast if the bottom one is lit. This system automatically makes you fly the correct approach speed regardless of weight. It works exactly like the indicator lights in an F-4 jet fighter, yet Mike built it for $5.00! Mike, how about a drawing of this for CP#18?

We have no reported VariViggen plans changes since CP16. We have been able to inspect the Melvill drawings for the worm-drive main gear modification. They do add some complexity, but in the long run we feel

that it's well worth it. We highly recommend it and plan to incorporate it when the Viggen plans are updated in the 2nd edition.

Jesse Wright is continuing to provide a very beneficial service in helping Viggen builders with his well-built parts and installation instructions. Thanks, Jesse - we've gotten a lot of compliments on your parts (Jesse's address is on the Viggen flyer).

Stall speed with 2 crew & 1/2 fuel	57 kt	56 kt

The RAF hangar is located on the west end of the flight line at the Mojave airport, Mojave Calif, approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any part for our comments. We are normally open from 9 to 12 and 2 to 5 on Wed thru Sat, but you should call first to check, since with the fly-in season starting we will be gone a lot.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder-question. Mark the outside of your envelope "builder question". This will speed our reply.

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY

The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73, and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips." Gas service and other airport services have been better, too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS:

AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow, Box 424, Fullerton, Ca. 92632 (714) 870-7551.
VariViggen spruce kit, plywood kit, hardware, aluminum and fiberglass. Catalog cost $2.

KEN BROCK MANUFACTURING, 11852 Western Ave, Stanton, Ca. 90680 (714) 898-4366.
VariViggen prefabricated components: all machined parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton, Oh 45424.
VariViggen plexiglass canopy.

MONNETT EXPERIMENTAL AIRCRAFT, INC, 955 Grace St, Elgin, Il 60120 (312) 741-2223.
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48706.
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509.
VariViggen welded nose and main landing gear, 1-1/4" sq. steel tube.

Box 561, Frankton, Ind. 46044

JESSE WRIGHT (VariViggen builder), 7221 S. Colorado Ct, Littleton, CO 80122 (303) 771-5140.

VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price: $10.00 first class mail, $11.50 air mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price: $6.00 first class mail, $7.50 air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, & flight reports as possible. Details mandatory, desirable, & optional changes to plans & to owners manual. A newsletter subscription and all back issues are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price: $4.75 per year first class mail, $6.50 air mail overseas. Back issues: $1.00 each

VARIVIGGEN PLANS - NASAD approved in "AA" category. Sixty-one sheets, completely detailed. Also included are builder's handbook information, step-by-step construction guide, complete bill of materials, flight operating limitations, parts lists. Section breakdown: 1. Introduction, 2. Operating Limitations, 3. Bill of Materials, 4. External Geometry (Lofting), 5. Building Tips, 6. Construction Order & Methods, 7. Canard & Elevator, 8. Fuselage, 9. Inboard Wing, 10. Verticals & Rudders, 11. Outboard Wings, 12. Cockpit & Seats, 13. Canopies, 14. Flight Control System, 15. Fuel System, 16. Angle-of-Attack System, 17. Engine Mount, 18. Cooling & Cowling, 19. Landing Gear, 20. Gear Doors, 21. Electrical System, 22. Parts List. Also included are the tech report & photo described. Price: $53.00 first class mail, $59.00 air mail overseas.

VARIVIGGEN SPECIAL PERFORMANCE (SP) WING/RUDDER PLANS - Construction drawings and assembly manual for glass composite outer wing panels and rudders. These are optional wings, replacing the aluminum surfaces shown in the VariViggen plans. The SP wings are easier to build and provide increased climb and cruise performance. They also have fuel tanks which increase range to over 600 miles. Price: $39.50 first class mail, $41.50 air mail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18%-size radio-controlled model airplane built & flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment & engine in the .35 to .65-cu. inch size. 555-sq inch wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price: $4.75 first class mail, $5.50 air mail overseas.

VARIVIGGEN CONSTRUCTION MANUAL Part 1 of a photo-illustrated construction manual, written by Jim Cavis, S/N 31. Includes fuselage,

canard, inboard wing, vertical stabs, control system, and landing gear, along with approximately 100 photos. Part 1 also includes helpful sketches on jigs and numerous building tips. The written information is similar to plans chapter 5, except expanded to about 30 pages. Price: $18.50 first class mail, $20.50 airmail overseas.

CP17, Page 12

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6', 5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included

basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION IIC - LYCOMING 0235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP @ GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm

BACK ISSUES - $1.00 each

If you are building a VariViggen you must have newsletter 1 through 18. If you are building a VariEze from the first edition plans you must have newsletters 10 through 18. If you are building a VariEze from the second edition plans you must have newsletters 16, 17 and 18. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave airport, Mojave, Calif., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any part for our comments. We are normally open from 9:00 to 12:00 and 2:00 to 5:00 on Wednesday through Saturday. If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder question." This will speed our reply.

RAF ACTIVITY since the July newsletter has included the Oshkosh EAA convention, completion of the basic flight tests on the Defiant twin, work on updating the VariEze section IIA and VariViggen plans, and builder support.

We are very happy to report that Mike and Sally Melvill (builders of N27MS, the beautiful VariViggen seen at Sun-N-Fun and Oshkosh) have moved to California and joined us here at RAF. Mike is now responsible for builder support on the VariViggen and is helping Burt by assisting VariEze builders. He is busy preparing the 2nd edition of the VariViggen plans, and will soon start building a VariEze. VariViggen builders are invited to RAF to inspect Mike and Sally's VariViggen. It has immaculate workmanship. It has composite glass/foam standard wings with wing tanks, full IFR panel, and is powered by a 180-hp Lycoming. Mike and Sally have used N27MS extensively for travel, logging 230 hours in the first year.

OSHKOSH 78 - Twenty-four VariEzes, one Quickie, and one VariViggen flew to Oshkosh, Wi., in July for the annual EAA flyin. It was quite a sight to see them together, particularly in the fly-bys. Mike's VariViggen and thirteen EZ's were airborne in the fly-by pattern at one time. The Quickie, EZ, and Viggen joined up in formation for airborne

photos to be used in "Poplar Mechanics" magazine. Fred Keller flew in from Anchorage, Alaska in his beautiful EZ that won our "Best VariEze" trophy and also the convention's "Best workmanship" award - this is the first time the workmanship trophy has gone to a composite aircraft. Fred's finish is flawless, yet his empty weight (no generator) is only 590 lb using the C-85-12 Continental. He attributes this to very careful and accurate foam core assembly with a minimum amount of micro used in core assembly and finishing. Maybe we can talk him into writing some words on his techniques for a future newsletter. Fred built most of the prefab parts, himself, keeping his total cost (including engine and shipping to Alaska) under $6000. Congratulations, Fred, for a well done project, and thanks for sharing it with all of us at Oshkosh.

Daily VariEze bull sessions were held at the EZ's on the flight line the first five days of the convention. Builders would ask questions and each of the EZ pilots would answer giving his experience. These were very educational for all. Subjects ranged from stall characteristics to UFO reports. A summary of the bull session information is shown later in this newsletter.

The first running of the Lowers-Baker-Falck race was during Oshkosh 78. This is actually an efficiency contest much like the Indianapolis 500. At Indy the cars are given 280 gallons of fuel for 500 miles. For the LBF race, the airplanes must finish 500 miles on less than 18 gallons of fuel. Four airplanes were entered: Steve Wittman with his Bonzo formula racer, Ken Rand with his Turbo KR2, Ken Swain, with his Lycoming-powered VariEze, and Dick Rutan with N4EZ, RAF's Continental 0-200-powered VariEze. None of the racers could run wide open, since they would burn more than 18 gallons and thus be disqualified, thus, the pilots had to carefully plan and adjust their speed. Any fuel left over (less than 18 gal) could be added to the speed at 1 mph-per-lb fuel. The 'O1 master' Steve Wittman won easily at an adjusted speed of 199.8 mph (fuel remaining 19.5 lb). Dick Rutan was second with an adjusted speed of 168.5 mph (fuel remaining 6 lb). Ken Swain was third with an adjusted speed of 157 mph (fuel remaining only 0.5 lb!). Ken Rand was disqualified for using too much fuel (10 lb over the 18 gal), his adjusted speed was 147 mph. Next year there is a four-gallon (24 mph) advantage given for two-place airplanes, so we can compete more favorably with the racers.

We want to thank the eager and able volunteers from the Minnesota VariEze club (see "CP" 14 for a list of clubs), who helped us throughout the Oshkosh week in our booth: George Wilson, Vic Berggren, Jim Tome, Cliff Johnson, John Novy, Earl Freeman, John Benjamin, Dennis Mitchell, Nat Puffer, and Ed Wieland. Jim Tome was the one who occasionally sported the "Darth Vader" costume. Nat Puffer's VariEze was the first to arrive and last to leave.

COMPOSITE WORKSHOP - VARIEZE, VARIVIGGEN, & QUICKIE
We are planning one more composite construction seminar. This will be done jointly with Quickie Aircraft, Inc., since the VariEze, VariViggen, and Quickie construction methods are similar. The seminar will be held at RAF, hangar 13, Mojave Airport on Saturday the 25th of November. There will be flight demonstrations of the Quickie, EZ, VariViggen, and Defiant between 10 and 11 AM. The workshop will run from 1 PM till 6 PM. Sandwiches prepared by the local Rainbow girls

will be available for lunch. Builders are encouraged to bring parts of their airplanes. If you have a part in which you are unsure of its workmanship or acceptability, bring it so it can be inspected or used to educate others. Mojave Airport is a two-hour drive north from Los Angeles on Highway 14, 25 miles on a 335 radial from Palmdale Vortac. Bring folding chairs if you can.

CP18, Page 1

A letter from Nat Puffer.

Dear Burt and Carolyn,

This is a special "thank you" letter. The VariEze has really changed our lives. Much has been written about how easy and satisfying it is to build a VariEze, and much has been written about how delightful it is to fly a VariEze. With all of this we concur. But not enough has been said about how owning and flying a VariEze can change your personal lives.

When you are building an airplane, you live in relative obscurity, except for other builders. You tend to shun social obligations, to get the plane done, and tend to drop out of things going on around you. But once the airplane is completed, especially a VariEze, it is an instant passport to fame. You become an instant celebrity! It is very ego building and in stark contrast to what has gone before.

It starts with offers of free use of airplane trailers, free hangaring and/or reduced rates. Very prompt attention from the FAA, etc. Every time we open the hangar doors, an instant crowd of admirers gathers. People come back time and time again, and just stand and look. Special recognition by the control tower. All kinds of people anxious to help in anyway possible.

Being reported as a UFO, and being interviewed on the radio. Being the subject of a sound movie, and being interviewed on the local TV station.

At Oshkosh, receiving a very warm and friendly reception by the control tower, and being personally escorted to a parking space right in front of the main gate. Being asked to participate in a fly by. Being asked to participate in photo flights in formation for Popular Mechanics, National Geographic, and Sport Aviation. Being asked to announce on the Oshkosh PA system for the VariEze fly by just before the airshow.

On the return home from Oshkosh, having Mpls Flight watch carry on a running conversation for 90 miles asking if I would land at Mpls. International so they could see my VariEze.

At Voyageur Village being swarmed with kids. At a local fly in at Osceolla, drawing the crowd away from all the other airplanes. Not being allowed to pay for my gasoline. Having the 3M employee Magazine editor asking for an interview, and having to fly a special photo flight for the company photographer.

Having everyone who flies in the other plane on a photo flight ecstatic over how much the VariEze excels any other plane in the sky. (I make gunnery runs and fly circles around the chase planes). Being very proud to be a part of the VariEze program.

Best of all, how ecstatic my wife is about being a part of it all, and how she simply eats it up! She delights in explaining all the intimate technical details to people, and how wonderful it flies. (She has never even had her hands on the stick and would be terrified if I asked her to fly).

There is no indication that any of this will ever let up. It has truly been one of the nicest things that has happened to us in our life time, and we owe it all to you, Burt and Carolyn.

Very truly yours,
Nat Puffer.

THE DEFIANT PROTOTYPE has now completed its basic flight test program, including high angle-of-attack tests. It has been equipped with a full IFR panel of King equipment, including their new integrated VOR/LOC/GS/DME/ RNAV KNS80 NAV system. It has logged 120 hours in its first three months, including trips to St. Louis and Las Vegas for the NBAA and AOPA conventions. Its longest leg was 1032 nm (1188 miles), flown at 12,500 ft at an average speed of 184 kt (212 mph), using 84 gal of fuel. It has been flown to 28,350 ft altitude. It can fly at 174 kt (200 mph) at 20,000 ft, with an economy of 13.2 nm (15.6 miles) per gallon! Rather than use the "CP" space to describe the Defiant we refer you to several articles and pilot reports to be printed within the December issues of "Flying" and "Air Progress" magazines. Defiant will also appear in "National Geographic" within the next year. We are presently gathering information to assist us in deciding how to proceed with the Defiant. Should we decide to do the type certification program ourselves, we may be soliciting investors to assist in financing the certification effort. If you, or someone you know may be interested in this as an investment, please write to Rutan Defiant, Building 13 Airport, Mojave, Ca. 93501. We will supply an introductory bulletin and contact you, should we require investors.

VARIVIGGEN NEWS - by Mike Melvill
The big news for potential 'Viggen' builders, at least, is that the plans for the VariViggen are being updated, corrected, improved and reprinted in a second edition. These plans will be more like the VariEze plans, in that there will be more "how to" instructions covering each chapter with photographs, wherever possible. Engine baffles will be shown full size in most cases with photos to clarify where each part goes. We will be incorporating all valid parts from Parts I and II of the VariViggen Construction Manuals. Photos and words from both parts will be included in the appropriate chapters. All corrections and revisions from newsletter #1 through #17 will be included. The foam-fiberglass composite S.P. wing, composite standard wing, rudders, ailerons, will be in the new edition. Also, since so many people have had problems with the cable system on the main gear, we will be incorporating the worm gear drive as used on my Viggen N27MS. This system has worked flawlessly for over a year now, the aircraft has 230 hours and 260 landings on it, with absolutely no problems. We will have the bearings, gears and machine parts available

at our normal distributors. The new edition of the VariViggen plans should be available by late November, 1978 and will consist of approximately 120 pages and will cost $165.00 Now that we have a VariViggen on permanent display here at R.A.F. it is available to all builders to inspect and compare. Hopefully we will be able to get the Viggen builders to start contributing to the newsletter again. We know there are a lot of active builders out there so how about it guys? Send in something for the newsletter. That is the only way we can get feedback and so help others who are building. We have had only 20 replies as a result of the requested survey in CP #16 so far. (Please send them in guys, it only takes a few minutes of your time, and it really is a big help to us). Even such a small number is still interesting and shows quite a wide distribution of Viggens through 14 states and three different countries. There are at least three Viggens flying now with several close to flying. The majority of those who sent in their survey replies appear to be between a year and two years away from flying. Wally Warners Viggen N455VV is once again airworthy after a main gear up landing sometime ago. Jim

---

Edgar of Columbus, Ohio, has begun his flight tests. John Poehner of Flushing Michigan, has his Viggen N29X, painted white and ready for first flights. He is awaiting hanger space.

My own Viggen, N27MS, has flown coast-to-coast and been to many states, as well as Florida's Sun 'n Fun and Oshkosh, where I had the opportunity to meet and talk with many of you Viggen builders. Both myself and my wife Sally are working full time here at R.A.F. and we are both looking forward to meeting more of you. Feel free to call or write either of us with your questions and or problems. Some of you have sent in suggestions and been disappointed when it was not printed in the newsletter. We have to decide what will be of help to the average builder and we have to avoid printing anything that may be confusing. Anyway, take heart and keep in touch with us, contrary to what some of you think, Burt has not abandoned the Viggen builders, quite the reverse, viz: new Viggen plans, Mike and Sally and N27MS hired on etc. We need to get the Viggen builders fired up again, it is a fine aircraft and you will love it when you start flying yours! I just recently learned to roll mine, and it is really quick and so easy to roll I wish I had learned earlier. I had not rolled it prior to coming to Mojave, as I had had no aerobatic training, but with instruction from Burt's brother Dick, I have been finding out just what a super handling aircraft the Viggen is. Dick's comment after his first flight in N27MS was, "That is the most responsive airplane I have flown since I quit the Air Force, I love it!"

Viggen builders should note the drawings for Mike's three-light angle of attack system shown later in this newsletter. This indexing system gives precise approach information without requiring the hard-to-find low-friction potentiometer.

VARIEZE SECTION IIA is now in its second edition after extensive modification to incorporate the three-tank fuel system ("CP" 11), revised exhaust systems, and some recent improvements to improve fire resistance and water removal. This involves moving the fuel valve

forward of the firewall, adding a gascolator (better water removal and removal of contamination-replaces the filter), and using a fire resistant line ("CP" 16) to the carb. There have been no VariEze fires, but we still think it's best to have the system meet FAR part 23 fire resistance requirements. These improvements are shown later in this newsletter, so those building from first edition IIA plans can update your drawings. Note that the valve is now a Weatherhead Delrin-spool type, to eliminate the valve sticking problems that occurred with the earlier Imperial valves. Our thanks to EZ builder Gordon Wright of Fort Jones, Ca., for suggesting the Delrin valve. Our tests show it to be compatible with avgas and to have excellent operating forces. Note that the improved fuselage tank now has its outlet in the front allowing positive water removal in the nosedown parking position.

SURVEY OF EZ'S FLYING - "CP" 16 included a data sheet. Enough of these have now been received to show some average results. Most of the approximately 100 owners that are flying have not supplied the information. Please do so, so we can get a better statistical average. The data is plotted below vs. engine horsepower. It shows that the average VariEze with a Continental is 30 to 50 lb overweight, 100 lb overweight for the Lycoming. Most of the airplanes over 650 lb are either loaded with equipment or are built with excess material than that shown on the plans. Remember, excess equipment or excess structure actually weakens the airplane. It can pull less 'g' and will fail more easily on a hard landing. The strongest airplane all around, is one built with all materials like the plans, with good workmanship, and kept as light as possible. Note that 25% of the airplanes (16% of the Continentals and 100% of the Lycomings) are over 650 lb empty. These are either single place airplanes or, at best, marginal with two people. The biggest surprise here is that all the Lycoming airplanes are overweight. The 0-235 weighs only about 15 lb more than a similar equipped Continental 0-200, and it is mounted closer to the cg, so we had expected similar empty weight. One possible reason is that some Lycomings are using mechanical and electric fuel pumps, but even this does not explain the large differences. So, those builders using 0235's have a goal - - who's going to be first to build a 600 lb. Lyc. EZ? It would be a performer, no doubt. Note that the lighter 0-200 airplanes will out-perform the average 0-235 airplanes. We do prefer the Continental if you can find one. The other plots show that, while some airplanes are meeting the performance shown in the Owners Manual, the average EZ is 12 mph slower, requires 170 ft more takeoff distance, and climbs slightly less. All responding commented that the owners manual adequately prepared them for first flights. While two owners reported they could beat the published landing distances, many listed long runway requirements under "dislikes", along with small baggage space, inability to use gravel and grass runways, low useful load, and forward visibility during landing. The owners listed the following under "what do you like most?" speed, fun machine, range, safety, economy, climb, appearance, everything, visibility, comfort and EZ to fly. All response under "problems or failures" were items that have been covered in previous newsletters. **GRAPHS OMITTED**

WEIGHT AND BALANCE - There have been several instances where builders have flown airplanes in a dangerous tail heavy condition because of

erroneous weight and balance data. This has occurred generally when using bathroom-type scales. Because of this we are now recommending that the measurements be done on a good platform scale. Only one is required, as long as two other stands are used under the other wheels so that the aircraft is level for all three weighings. One of the problems in weighing an EZ is that the main gear spreads out when the airplane is lowered onto the scales. This binds the scale sideways. To avoid this, align the scale so its wheels are pointed to the side or use two aluminum or steel plates under one wheel. Apply a generous glob of grease between the plates. This allows them to move sideways without binding the scales.

NEW DESIGN NG15 TESTED - The lower nosegear strut attach casting on the VariEze has been a problem for many builders. Last March it was solved with the addition of the NG25 plate and elimination of the bolts through the strut (CP16). Recently Brock ran out of the NG 15 castings so we made new tooling for it to improve its fit to the strut and to eliminate NG25. This new part (NG15A) fits over the strut and has a full length bottom plate that bolts on with four bolts (see photo). The entire strut and fork assembly was tested to more than 80% over the FAR Part 23 requirement without failure. The new NG15A is available now from Brock for new construction. Retrofit is not required provided your old NG15 is installed per "CP" 16 using NG25. Strength is equivalent.

VARIEZE PROPELLERS - John Benjamin, 973 Nissley Rd, Lancaster Pa 17601, is now producing and marketing the Sensenich Propeller for the VariEze (model W58LKL67). We have tested this prop extensively on N4EZ. Its performance is very similar to the Ted's prop and it appears to be quieter. Quality is excellent with 15 laminations and a plastic leading edge.

BUILDER HINTS.
Engine Instruments - The Westach Cylinder temp system is not temperature compensating. This fact is not clear in their supplied information. This system measures temperature differences between the probe and the wire junctions, with zero difference referenced to 70 degrees F. Thus, on a hot day with the wire junction temp of 100 degrees, the gage will read 30 degrees too low. At 40 degrees it reads 30 degrees high. Many, including us, have found the Westline oil pressure system to be unsatisfactory. We recommend a direct-type system for oil pressure.

3M makes a "white cap system" that may provide sufficient protection for those people who are sensitized to epoxy fumes. This is a helmet with a fresh air pump and filter. For details write, Occupational Health and Safety Products, 3m Company, P.O. Box 8327, Dept F3, St. Paul, Minnesota 55113.

Tach wiring - Plans show the electric tach wired to only one magneto, such that mag drop is only indicated on one mag - the other is done by 'ear', comparing it to the other mag. If you want to measure the drop on both mags do not hook the tach to both mags. Nat Puffer flew his first ten hours with a missing engine due to this. He came up with an excellent solution, which substitutes a double pole switch for one of the single pole mag switches. Wired as shown it switches the tach to

the mag being checked during the runup, with no "crosstalk" between mags.

Tires - we have seen several instances where the two ply VariEze tires have broken down before wearing out. Be sure to keep proper inflation - 55 psi on two ply and 65 psi on four ply. Replace the two ply tires after 60 landings even if not worn out. Better yet, use only the four ply rated tires.

Rod Ends - Reminder from "CP15" Page 4: we recently observed an airplane with a rod end that had been bent when installing the canard. Be extremely careful when the pushrods are loose that the rod ends are not stressed (bent). If you even suspect that a rod end has been slightly bent, ground your airplane until it is replaced. Nylon Control Conduit - we have an indication that incorrect material was shipped to some customers during the spring of '77. This was .039 wall nylaseal rather than the correct .025 wall nylaflow. Check yours, the 3/32 cable will not fit the incorrect tubing.

Epoxy Pump - when changing from fast to slow hardener merely hold the resin lid on while you tip the pump to pour out the hardener. Refill with correct hardener. The mixture of fast and slow obtained by residual material is good - no problem.

Fiber Orientation - at least two builders have built wings with all the UND plies parallel to the T.E. rather than one parallel to the L.E.. Be careful to do this correctly, as we have no acceptable repair for this error, short of redoing the entire wing.

Dry Micro Fill - Bill Talutis suggests filling the T.E. depressions with gobbed up dry micro, cover with a peel ply strip, then using a putty knife at 45 degrees angle to smooth it down flat. The peel ply keeps the micro from building up and sticking to the knife. Remove peel ply after cure.

Elevator Trim Authority - some EZ owners have had insufficient high speed or low speed trim authority. If, after checking your trim spring rigging (CP 14 Page 5), you still require trim to fly hands off, install a trim tab on the elevator as shown. Bend the tab up for more up trim or down if you need more down trim. **SKETCHES OMITTED**

VARIEZE PLANS CHANGES - Incorporate these NOW

Section V Page 6	After "sand the surfaces lightly by hand" add "using 36-grit (featherfill requires a mechanical bond so do not use fine sand paper)" Add "do not wet sand featherfill, it absorbs moisture. Featherfill cannot be used over primer. 3M sanding screen type 18N FABRICUT WET OR DRY silicone carbide 180 works excellent on featherfill. It is available at lumber yards.
Section IIA & IIc 1st edition only	Install the gascolator, fire resistant fuel lines and valve as shown in this newsletter.

Owners Manual Page 31	Strike reference to bathroom scales. Add "align the scales or use grease plates to avoid side loading scales."
Newsletter 17 Page 5	Clarification - the wide chord elevator must be balanced to the same criteria as the original one. This may require additional lead weight. The additional weight should be added to both the inboard and outboard arms. This may require enlarging the slot in the canard at the outboard arm. Do not fly a new airplane without the wide chord elevators installed. Bruce Muirhead has flown his EZ with both the original and the wide chord elevator configurations. His comments "I flew my VariEze first with the original chord length and had the anticipated difficulty bobbing up and down on take-off and landing. After a couple rather hectic hours (and the realization that the elevator bottoms were not flat) I decided to extend the chord. The most important improvement I see is at take off. Now I can pretty well establish a good solid nose-off attitude at about 55 mph and hold it there while take-off speed is gained. Then the take off is positive and "up and away."
Section I Chap. 15	Add "Check to see if the seat belt brackets are radiused where the nylon belt loops through. Radius any sharp edges to avoid cuts in the strap"
Section I Page 12-3 CP 12, pg 7	Change toe-in angle to 1/4 to 1/2 degree. Excess toe-in causes excessive tire wear and increases the speed for nose rotation.
Owners Manual Page 17	Under "Tie Down" add "normal care of the main landing gear should always include lifting one wing tip to allow the gear to spring inward when parking, especially in hot weather. This reduces the possibility of gear creep and loss of alignment. Gear creep should not occur unless the airplane is overweight".
Section IIA	Change tygothane part numbers from 0505-107 to 0585-107

SHOPPING - Engines for sale: C85-8FJ call Pastor Jenkins (517) 626-2145. O-200 modified for 100 11, call Dave at (305) 425-2850

Wanted: Used epoxy pump - Ralph Freshour (213) 673-2819

Custom aircraft parts, 1318 Gertrude, San Diego, Ca 92110 is now making a muffler system similar to the flight research mufflers.

Aircraft Spruce's new catalog has been expanded to 230 pages, including 17 pages on composites (materials, tools etc).

OSHKOSH BULL SESSION RESULTS.
Stall Characteristics - all but two reported that stalls were as described in the owners manual. One noted that his would roll off after about three cycles of wing rock. One reported that at aft cg, his airplane would roll abruptly when he approached full aft stick and result in large altitude losses.

Trim change in rain - Based on the Bull session and on the test several owners made returning from Oshkosh, VariEze's all have a nose up trim change when in mist or light rain - this occurs even before the mist is seen on the wind shield. In moderate to heavy rain some VariEzes trim nose down.

Antennae Performance - while most have satisfactory reception, many have had poor results. The H & C antennas are working well with most of the lower cost radios, but the higher output units have had interference and some have had to mount the antennae farther from the radio, or use an external antennae. Nat Puffer reports good results using homebuilt antennas shown in EAA "Sport Aviation," October '76 issue.

UFO Reports - Three of the EZ's had been reported as UFO's in separate incidents.

Exhaust Systems - Two at Oshkosh had the mufflers, most had combinations of either straight stacks or the short double-bend tubes. Herb Sander's airplane had a system with flex joints and exits at the cowl T.E. near the prop tips. This simplified cowl removal. We asked Herb to keep us informed on how it held up after 100 hours since if it is durable we would like to get someone to produce it. How about it Herb? Let us know. By the way Herb's trip to Oshkosh from Memphis with his wife was the first time his airplane had flown two-place. His first flight was only seven days earlier.

Pitch Sensitivity - Nearly half the owners reported their airplanes were initially difficult to control in pitch until they got used to the sensitive forces. None at Oshkosh had the wide-chord elevator.

VARIEZE STALL CHARACTERISTICS AND FLIGHT TESTING
As discussed in the owners manual, "CP14, 15 & 17" not all VariEzes have the safe stall-proof characteristics intended. While the exact reasons for this are unknown, we have traced it primarily to cg position. For example, Lowell Ridge of Reno experienced a spin while doing stall tests on his first flight. He later found his weight and balance was incorrect and he was operating aft of the cg limit. He now reports standard stall characteristics at normal cg positions. Two EZs have reported bad stalls with large altitude loss, even at normal cg positions. As we have said before, a new homebuilt can be full of surprises in many ways: systems operation, flying qualities, performance, spin characteristics. This is to be expected from airplanes built individually without tooling and with a near infinite variety of things that can be slightly different.

The important thing that you must do as an individual is to realize that there is an enormous difference between flying a new untested homebuilt and flying a rented Cessna. You have the responsibility for conducting a safe test program and envelope expansion. Any time you expand the parameters (stalls, cg range, dive speed, load factor, gross weight, etc.) you should do it with a parachute and at least 8000 ft altitude AGL.

I have flown first flights on eight different canard homebuilt airplanes and have found the correct, docile stall characteristics on all of them. But, this does not mean that I would test the next one, opening the envelope of operation, without a parachute or without expecting to find something different. Never fly a new aircraft slow and low until you know its slow speed characteristics as tested at an altitude that allows a safe recovery.

ACCIDENTS There have been two fatal VariEze accidents since August. We presently have very little information on these, as FAA has yet to release its findings. The following information is listed here not to infer that we know the causes, but in the hopes that knowledge of the circumstances may in some way prevent reoccurrence. The first was one of the airplanes that was at Oshkosh. It had a total of about 60 hours flying time. It was sold to two people. One of the new owners had no problem flying it and made several flights without incident. The other partner had considerable difficulty flying the aircraft but landed safely. On his second flight he was observed to be flying erratically on takeoff and during climb. He apparently approached much too slow, as the airplane was observed in wing rock at about 50 ft. height (+ 45 degrees bank angle). The aircraft fell at a high sink rate from about ten feet height, possibly damaging a wing tip or rudder at initial impact. At initial impact, power was applied, presumably for a go-around. The aircraft bounced nose high and abruptly turned left, then rolled left, striking the ground in an inverted attitude.

The second accident occurred on the third flight of a new airplane. The pilot had noted on the first flights an inability to trim the airplane, having to push on the stick to hold it level. The owner had neglected to trim the canard length, even though the airplane was tail heavy. He had not installed the wide chord elevator and did not correct the elevator shape even though it was similar to the "dangerous" one shown on "Page 11 of CP 17. On his third flight he was observed to be lowering the nosegear on final about 400 feet altitude when the airplane pitched up abruptly and rolled until striking trees in a near vertical attitude.

17 plys of UND & BID on a 32-ft wing takes 12 hours!

AOA indicator on Mike's Viggen. See page 13.

Viggen, EZ, Quickie, Defiant.

THIS PAGE IS FROM SECT IIA 2ND EDITION

FUEL SYSTEM

The fuel system consists of two wing tanks and a small fuselage tank, all equipped with visual sight gauges. A three-way selector is located on the pilot's right console. The selector is positioned left to select wing fuel, up to select fuselage fuel, and right to off.

The wings hold about twenty-four gallons total, all is usable for climb or level flight. One to two gallons per tank are not usable for steep descents. The fuselage tank holds about 2.8 gallons, all is usable in all normal attitudes.

Drains are provided at the wing tanks and at the gascolator. The wing tanks are vented together to maintain equal tank fuel levels. The fuselage tank has a separate vent to provide redundancy from a clogged vent. The fuel selector handle is designed to interfere with the pilot's wrist when the fuselage tank is selected, as a reminder to not takeoff on fuselage fuel. Fuselage fuel is only used as the last fuel on a long trip. This allows complete use of the wing fuel and a very accurate indication of the last 1/2 hour fuel supply.

Do not delete the fuselage tank. Without it, the unusable fuel for descents of about three gallons becomes just "dead weight." Thus, by adding the 2.5 gallons, you are adding about 5.5 gallons of usable fuel (over 150 miles range) and providing very accurate gauging of the last 2.5 gallons. Note that all the wing fuel can be used in level flight. It is not unusual to completely run the wings out during cruise, select fuselage to restart and continue, on fuselage fuel. See "Owner's Manual" (2nd edition) for operation of the fuel system. **SKETCHES OMITTED**

The schematic shown below shows the general arrangement of the entire fuel system. Details of each area are covered in other parts of this manual. **SKETCHES OMITTED**

CP18, Page 7

THIS PAGE IS FROM IIA SECOND EDITION

FUSELAGE TANK

Refer to "Section I," chapter 22, step 3. Do not install the urethane foam along the rear of the plexiglass. Cut the FT30 bulkhead from 9 mm, 6-lb PVC to fit as shown to the firewall. Attach it temporarily with a couple dabs of 5-MIN. Cut out FT31 from 9 mm PVC foam, heat-form it (in an oven at 300 degrees F or with a high-watt hair dryer or heat gun) to fit around the top between the plexiglass and the firewall. Trim as required. Mount it with micro to the plexiglass and with 5-MIN dabs to the firewall. Now, complete step 4 and 5 of chapter 22. When cutting off the canopy (page 22-4) change the 4" and 5 1/2" dimensions at the back to 5 1/2" and 8" respectively. Fabricate FT32 bulkhead and FT33 bottom pieces to fit as shown, leaving room at the bottom sides for the shoulder harness attach points and main wing vent tubes. These parts are not dimensioned. They have to be custom-fit due to variances in canopy size.

Cut the tank away from the fuselage, leaving the small side pieces in place. Bond the FT30 and FT32 to FT31 with wet micro holding in place to cure with nails. Place a strip of Vinyl tape or shiny-surface duct tape on the inside of FT32 where the visible fuel gauge is located. Layup one ply BID at 45 degrees on the entire inside and on the inside surface of FT33. This layup should be wet to avoid pin holes.

Mount the fuel outlet in the forward center of FT33. The outlet is a 6-inch length of 3/8-inch soft aluminum tube. Sand its surface dull for bonding. Mount it at an angle as shown to bond along about 2 inches of the tank inside bottom. Flow in a liberal amount of wet flox and cover with 1 ply BID. This gives the outlet extra durability so it will not break loose. Before bonding, form the outlet so it will eventually lie along the front face of the center-section spar and not interfere with the hole in the spar or shoulder harness attachment. The outlet should not be bent after it is cured, as this can induce cracks or leaks. Fabricate a screen and install as shown in "Section I," page 21-4.

Now, bond FT33 to the tank with flox. When cured, remove the foam from the face of FT32 over the vinyl tape and remove the tape. Be sure the outlet is open to relieve any pressure during cure. Round all edges of the tank and glass it with two plies BID, lapping 1" onto the existing glass on the outside surface of FT31. Use peel ply to transition the exposed edges. Be careful to get no traces of micro on the visible fuel gauge. The gauge gives a good visible indication only if it is not contaminated with micro foam or air.

When cured, test for leaks using an altimeter with 1500-ft pressure. Identify any leaks with soap bubbles applied with a brush. Rinse and repair per "CP" 14. Cut a 2-1/8" hole in the top using a hole saw. Clean out contamination with a vacuum cleaner (tape a 1-inch tube to the hose to reach in). Bond in the Brock VariEze fuel cap (FT18). Drill a #40 hole in the cap to provide a vent.

Mount the tank to the fuselage with a 1-ply BID strip all around its edges. This will allow it to be removed if later required. Drill a 1/2" hole in the aft seat bulkhead for the 3/8" ID x 1/16 wall Tygothane tubing.

SKETCHES OMITTED

THIS PAGE IS FROM IIA SECOND EDITION

FUEL VALVE INSTALLATION

Locate your Weatherhead #6749 valve. Remove its handle and disassemble the valve. Carefully remove any burrs in the valve ports that can scratch its Delrin plastic spool. Chuck the handle stem in your drill and using emery paper remove enough of its diameter so it will slip inside the valve torque tube. When about .007" is removed it will slip inside the 3/8 x .035 2024T3 tube. Reassemble valve.

Cut the alum tube to 68.5 inches long. Mount the tube to the valve with two #8-32 screws as shown. Fabricate the FV1 plywood piece and bolt it to the valve with two AN4-6A bolts.

Fabricate the FV2 plywood piece and mount to the right forward armrest as shown in the upper right of page 19-5 of "Section I" (2nd edition). Fabricate the handle and drill it into the tube, clocking so it will be outboard for "off," up for "fuselage" and inboard for "wings." Do not mount it until final installation.

Now, grab the tube/valve/FV1 assembly and thread it into the fuselage passing through the CS118 hole in the backseat area and through FV2. The tube will have a gentle bend and should not bind on the seat bulkheads. When you are satisfied it fits well and clears all controls, bond FV1 to the fuselage side and let cure. Then remove the two AN4-6A bolts, remove the valve and layup 1 ply BID on each side of FV1 lapping onto the fuselage side.

Round up the plumbing parts shown and install them on the three valve ports using Teflon tape. Install the Tygothane tubing with the hardware shown. Do not substitute vinyl, polyethylene, polypropylene or Tygon tubing. They are not near as tough, are not fuel compatible, and get brittle at low temperatures. Tygothane has a tensile strength of 5900 psi and avoids brittleness down to -100 degrees F. Mount the gascolator on the firewall and plumb the aluminum line as shown (pg 17). An alternate (better) method is to use the gascolator installation bracket shown on page 100 of the 1978 Aircraft Spruce Catalog which mounts the gascolator with one port facing the firewall to allow direct routing of the fuel line through the firewall.

SKETCHES OMITTED

CP18, Page 9

THIS PAGE IS FROM IIA SECOND EDITION

SKETCHES OF VARIEZE FUEL SYSTEM OMITTED

- - - - - - - - - - - - - - -

EXHAUST SYSTEM

The preferred exhaust system for the VariEze is the system consisting of two mufflers, one on each side, directly below the exhaust ports. This is similar to the system on Cessna 150's. The mufflers reduce the noise level and provide excellent heat for carb heat and cabin heat.

Use Continental exhaust gaskets (part no. 21493) on final installation. For initial fit-up purposes, don't use your gaskets. The initial "set" taken by the gaskets when the flange is torqued down provides a custom seal for that exhaust pipe and several cycles of installation and removal reduces the effectiveness and life of the gasket. Use 5/16 x 24 brass exhaust manifold nuts with AN960-516 washers (8 ea) for final installation. Be sure to install the support on the right muffler.

The mufflers require a homebuilder-fabricated blister to fair them in to the cowling. This job is not as difficult as it appears. When

fitting the cowl, cut a hole to clear the mufflers by 1/2-inch all around, plus clearance to hookup the heat muff hose. Put the mufflers and cowl on. Using some soft wire (coat hangers) make three or four "templates" to define the shape of the blister to clear the mufflers by about 1/2 inch all around. Remove cowl and place on a table upside down. Tack a large block of foam (green or blue) on the cowl and carve to a pleasing shape that clears the mufflers. Line the edges with gray tape to provide a release then glass with four plies BID. Remove the blister, and dig out the foam. Sand the cowl surface and attach the blister with flox and pop rivets with 3-inch spacing. Leave about 1/4" space around the muffler outlet pipe so the excess muffler heat can escape.

You will be surprised at how little cabin heat is required for a VariEze. In general, the natural solar collection of the canopy and insulation of the cockpit will provide sufficient heat for day/VFR flying, as long as the canopy is well sealed. N4EZ's cockpit temperature can be maintained at 65 degrees f with an OAT of 25 degrees f. In the summer heat, the cockpit is well cooled by opening the vent.

We recommend that you do not install cabin heat, to save weight & complexity. If your flying experience indicates you need it, it is easily added later by adding a tee in the carb heat hose and plumbing a 2" dia (1 1/2 may be enough) hose to the feet area of both cockpits. Install an adjustable valve in the line to control the amount of heat.

SKETCHES OMITTED

THIS PAGE IS FROM IIA SECOND EDITION

A less expensive, lighter, and louder system can be made as shown with three straight stacks and one double elbow. The double elbow is used on the left forward cylinder to provide sufficient pipe length for a carburetor heat muff. The heat muff consists of a over-stretched screen door spring wrapped around the pipe to transfer heat and a sheet metal shroud wrapped around the area to collect heat. Note that this pipe must be supported to the cylinder by the tube shown, to prevent vibration failure. The three straight stacks are equipped with safety cables to retain them, should they fail at the flange. This keeps them out of the prop. Do not omit this!

Various other exhaust systems are presently being developed and tested. As they prove successful they will be defined in the "Canard Pusher" newsletter.

SKETCHES OMITTED

THIS PAGE IS FROM IIA SECOND EDITION

HEAT MUFF

Cold air enters at the ends and at the right side and is warmed by the hot pipe and hot spring, before being drawn off at the 2 1/2" tube at left center. **SKETCHES OMITTED**

To fabricate the spring, take a 1/2" dia screen door spring and over-stretch it so the gaps in the wire open to about 1/10". Attach it to one of the tabs with 3 loops of .041" dia stainless safety wire. Wind it tightly around the tube and attach to the other tab.

The muff shroud can be built by forming a flat sheet of .025 6061T6 alum to fit over the spring wrap as shown. Cut the outlet hole and weld on a 3-inch length of 2 1/2" dia 6061-T6 tube. Fasten as shown with three #8-32 screws and locknuts.

Support - This tube must be supported to prevent vibration-induced failures. **SKETCH OMITTED**

The support can be a 1/2 x .035 steel tube. Heat the ends red-hot and flatten. Bolt to the welded tab on exhaust tube and bolt to a valve cover bolt on the engine.

Install a 2-1/2 diameter SCAT-10 (RED) induction hose from the air valve to the muff. Follow the clamping details shown on page 17. This hose should be retained against the engine mount with a nylon "tie wrap". So that it doesn't chafe against the cowling.

CP18, Page 12

ANGLE OF ATTACK VANE AND SWITCHING GEAR.

The pivot is made up of a 1 1/4" length of 5/8" - .062 aluminum tube, with an MRC R 3ZZ bearing (or equivalent) pressed into each end. The spindle is a .187 dia. stainless steel rod, 1 3/4 long. This is pressed into both bearings as per drawing. If it or the bearings are loose, use Loctite to be sure the spindle and bearings are firmly located, but free to spin. An aluminum vane is attached per drawings to the outboard end of the spindle. This vane can be carved from solid aluminum, or fabricated. An aluminum arm is cut from 3/16 stock with a balance weight as shown. Install the vane and balance arm on the spindle and balance them by grinding the balance weight down. The brass brushes are cut from .005" brass shim stock. These are split back from the contact end to the mounting area, as shown in the enlarged detail (no scale). The switching board is a piece of copper clad circuit board, obtainable from Radio Shack. Lay it out as shown. The detail is full size, and may be scaled. Remove all the copper cladding except in the areas shown. Drill three small holes where indicated, and push #22 wires through from the back side and solder to each copper area. These wires go to the light bulbs in the three light A.O.A. indicator, mounted on top of the glare shield or high in the panel. The circuit board is epoxied to a piece of 3/8" thick phenolic. A 5/8" hole is drilled through the circuit board and phenolic block. A #10-32 set screw is installed as shown to lock the circuit board and phenolic block to the 5/8" spindle housing, and to serve as a ground wire attach point. A similar phenolic block is epoxied to the inside of the nose cone. A 5/8" hole is drilled through the phenolic and the nose cone skin. A #10-32 set screw is installed in this block, is used to fine tune the A.O.A. vane.

When flying the A.O.A. indicator, only the green light should be on when the airplane is "on speed" on the approach. If you increase the airspeed by about three knots indicated, you will have the green and yellow (lower) lights on. Further increasing the airspeed by three knots will leave only the yellow light on. Slowing the airplane down three knots (increasing angle of attack) from a green light (on speed) will switch green and red (top) lights on. Reducing speed three more knots leaves only the red light on, indicating too high of an angle of attack (too slow). This is a simple yet very effective way to achieve consistently good landings. The A.O.A. indicator is wired through the gear down and locked, and therefore is an excellent gear up warning.

For first flight in a VariViggen, set the vane at 11 degrees - 12 degrees up with the bottom of the airplane level. The vane pivot must be set at F.S. 9" and W.L. 12". Then adjust as req'd to obtain the correct speeds.

Special Performance Wing	Gross Weight	1700 lb

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-

ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY.
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.
AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow, Box 424, Fullerton, Ca 92632 (714) 870-7551
VariViggen spruce kit, plywood kit, hardware, aluminum and fiberglass. Catalog cost $3

KEN BROCK MFG. 11852 Western Ave, Stanton, Ca 90680 (714) 898-4366
VariViggen prefabricated components: all machined parts. Catalog costs $2

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton, Ohio 45424
VariViggen plexiglass canopy. (513) 845 9872

MONNETT EXPERIMENTAL AIRCRAFT, INC., 955 Grace St, Elgin, Il 60120 (312) 741-2223
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City Mi 48706
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509
VariViggen welded nose & main landing gear, 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, CO 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air mail- overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail- overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues starting with CP#19 are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price - $4.75 per year first class mail, $6.50 air mail overseas. Back issues, $1.00 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the past several years. It covers the entire airplane, including the engine installation, fuel system, and not only covers the original standard wing in both aluminum and foam and fiberglass composite, but it also includes the composite S.P. Wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio-controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65-cu inch size. 555-sq inch wing area.

All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price - $4.75 first class mail, $5.50 air mail overseas.

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability,

dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6', 5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION IIC - LYCOMING 0235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS & PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP @ GROSS WEIGHT:

Take Off	900 ft
Climb	1600 fpm

THE CANARD PUSHER NO. 19 JAN 79

Published quarterly (Jan, Apr, Jly, Oct.) by
RUTAN AIRCRAFT FACTORY
Bldg. 13, Mojave Airport
Mojave, Ca. 93501
(805) 824-2645

U.S. & Canadian Subscriptions - $4.75
Overseas (AIRMAIL) - $6.50
Back Issues - $1.00 each

If you are building a VariViggen from 1st edition plans you must have newsletter 1 through 19. If you are building a VariEze from the second edition plans you must have newsletters 16 through 19. A current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any part for our comments. We are normally open from 9:00 to 12:00 and 2:00 to 5:00 on Wednesday through Saturday. If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions." This will speed our reply.

RAF ACTIVITY since the July Newsletter has involved some new developments in support of VariEze builders. We are now introducing two important new improvements for the VariEze - a wing leading edge cuff to improve stall margin, and a crank-type nose gear actuator.

Approximately 25 new VariEzes have taken to the air since the last newsletter. Our prototype, N4EZ now has 400 flight hours.

Our Defiant, VariViggen, and VariEze have all been flown extensively lately, logging about 150 flight hours since October.

The NASA skew-wing AD-1 successfully completed its static load tests. It will be delivered to Edwards Air Force Base next month for research flight tests. This is the first non-homebuilt aircraft to use the structural methods developed for the VariEze. Ames Industrial Corp. should be congratulated for building the AD-1 "on-cost" and "on-schedule". This is rarely accomplished by the large aircraft companies.

THE COMPOSITE WORK SHOP held at RAF on 23rd November, was attended by over 350 people! In addition to the fiberglass education, an airshow was given. It included a Quickie flight demo and a three-ship

formation with the Defiant, VariViggen, and VariEze. We hope to make the workshop an annual event.

THE QUICKIE PROTOTYPE now has 250-hr flight time. Tom and Gene report an operating cost of $3.25-per-hour for the last 14 months, including fuel, oil, maintenance and insurance. Quickie has orders for 185 kits and has delivered 125. About six homebuilt Quickies are nearing completion. Quickie Aircraft Co. plans a seminar tour this spring, flying N77Q to several cities. Details on this will be in the April Quickie newsletter. For the newsletter or any details on Quickie, contact them at Quickie, Bldg. 68, Mojave Airport, Mojave, Ca. 93501 (805) 824-4313.

PHOTO OF VARIVIGGEN, VARIEZE, QUICKIE AND DEFIANT OMITTED

Bob Hoover, after his flight in the Quickie. Bob also flew the Defiant last October during the Mojave Air Races. **PHOTO OMITTED**

THE SECOND EDITION OF THE VARIVIGGEN PLANS has finally been completed. Our apologies to those who were told it would be available in November. It was just a much larger job than we estimated. Mike has been working over three months on this package now. It includes all the information previously included in the 1st edition plus the two construction manuals, the S.P. wing plans, a new composite "standard" wing section, additional construction hints, the Melvill-designed worm drive main gear and our "Moldless Composite Aircraft Construction" book. Of course all improvements incorporated since the beginning have been included. The second edition VariViggen plans are more than double the number of pages of the 1st edition. Many of the parts are now shown as full-size patterns. We expect the 2nd edition from our printer by mid February.

DEFIANT FILM - Ferde Groffe Films is now finishing a new sound movie on the Defiant. Flying for this film was done in December. We understand it is even more spectacular than their Award-winning "Flying is VariEze" film produced in 1977. The new film shows the Defiant being put through its paces including loops, rolls, single engine takeoffs and an exciting comparison of it and a Beech Baron. Ferde is well known for his artistic blending of film and music. The new Defiant film is available from Ferde Groffe Films, 18139 Coastline Drive, Malibu, Ca 90265 (213-454-3886). Write them for purchase or lease terms. It is available in 16 mm and super 8. Prices are similar to the VariEze film.

DID YOU KNOW that a 100 hp. VariEze can climb over 25000 ft. without turbocharging? Dick Rutan flew N4EZ to 25,300 ft on November 30, 1978. At 25,000 ft it trued out at 125 mph at 2100 rpm and 11-in manifold pressure. At 20,000 ft, maximum speed was 148 mph. Temperature of the cockpit remained 40 degrees above outside, despite the absence of a cockpit heat system. Takeoff gross weight was 890 lb. including 12 gallons fuel and 15 cu.ft. of oxygen. The structure remained below minus 30 degrees C temperature for half-hour. There were no indications of structural deterioration.

On November 7, '78, our Defiant light-twin prototype made a flight to determine its maximum endurance. The airplane was topped off with its normal load of 90.5 gallons and flown solo by Dick Rutan. He took off at 8:47 a.m. and landed at 23 minutes after midnight - a total flight time of 15 hours and 36 minutes! The Defiant's accurate fuel gage system allowed Dick to land with confidence, with only 2.5 gallons of fuel remaining. Both engines were run for the entire flight. The average fuel flow was 2.8 gallons per-hour per-engine, approximately 20% power, 1700 rpm and 13 inches manifold pressure. Mixtures were set at peak EGT. Speed ranged from 86 kt indicated at the start to 80 kt when low on fuel (maximum endurance speed). Distance traveled was nearly 1400 nm (1610 statute miles). Oil used was 1.1 qt-per-engine. Note that this data was obtained with fixed-pitch props whose efficiency is poor at low speeds. Maximum range at best range speed is about 1480 nm (1700 statue miles), with a light payload. This efficiency is a direct result of the canard arrangement with winglets - giving very low induced drag.

We have service-tested the Defiant prototype extensively and found that it can indeed provide utility not found in conventional aircraft. Examples: Los Angeles to Norfolk Va. with one stop in Dallas, cruising at 17,500 ft. Upon arriving at Norfolk we made two practice instrument approaches, landed, flew a 30 minute demo flight loaded with NASA personnel and then fueled the aircraft - 45 minutes of fuel remained! More significant was a trip from El Paso to Los Angeles with 600 lb cabin load, into 45 kt to 65 kt headwinds, in cloud and rain for 2 hours and had to climb to above 14,000 ft to shed rime ice. Airports enroute were below IFR minimums. A conventional light twin could not have made that trip. The Defiant landed in Los Angeles with two hours fuel!

WING CUFF IMPROVES VARIEZE STALLS - As you know from newsletters # 14, 15 and 18, not all the VariEzes flying have reported the safe, departure-free stall characteristics. Several aircraft have reported highly divergent wing rock or an abrupt roll-off into a nose down rolling dive resulting in a large altitude loss, when near full aft stick at aft cg. In late November, Dick was demonstrating stalls, with David Record in the back seat of N4EZ. After showing the stall resistance by level and turning stalls at full aft stick, including sideslips and reversals, Dick let David do some stalls from the back seat. In one of David's stalls, the airplane abruptly rolled left and appeared to spin one and half-turn before recovering, with a loss of 1200 ft altitude. This, of course was quite a shock, since we had never experienced a departure from controlled flight with our VariEze. A post-flight weighing revealed that the cg was within a half-inch of the aft cg limit.

We then initiated a complete series of new stall/spin tests with N4EZ to try and further quantify its stall resistance. The airplane was ballasted to various cg positions and tufted to visualize airflow. Dick flew the test flights. A summary of the results follows:

The aircraft was totally immune from stall departures or loss-of-control regardless of control inputs or attitudes or power setting as long as the cg was forward of F.S. 101 (short canard, 142 inch span). The following applies to its characteristics when the cg was aft of F.S.101: The aircraft was immune from loss-of-control or departure

when maneuvered, ie, attempting accelerated stalls. It was also immune during low-energy entries, ie, hammerhead stalls or tailslides. However, occasionally the characteristic wing-rocking motion would diverge and result in a departure to the left within about four cycles of wing rock, at one - g flight. Also, occasionally the airplane would depart in roll to the left without wing rock if the speed was about 48 knots (one-g, level or mild nose-up climb). The departure at first appeared to be entry into a steep spin, since rotations up to one and half "turns" were experienced. Recovery was prompt, as the the stick was pushed forward. We soon realized that the departures were not spins, as the angle-of-attack was rapidly decreasing and the motion was quickly converted into roll, i.e. there was no stable spin mode. To prove this, full pro-spin controls were held in (aft stick, left rudder), rather than attempting recovery. With these controls held in, the airplane's recovery was just as rapid as when recovery controls were used. Thus, rather than a spin, the aircraft was experiencing a "rolling departure". In military stall testing with fighters, we called these maneuvers "recovery rolls" or "augers".

The good news is, of course, that stable spins were not possible. The bad news is that the aircraft is susceptible to departures with altitude loss as great as 2000 ft when near aft-limit cg. It would be easy to merely brush this off as "normal" and stress the usual training lesson of speed control to avoid stall. We refuse to do this, because we have always been proud of the departure-resistance of a properly-designed canard airplane. Thus, with the help of NASA at Langley Va. we developed a solution. Joe Chambers at NASA had been conducting dynamic wind-tunnel tests with a model of the VariEze. He found that a partial-span drooped "cuff" that extends forward of the leading edge produced a vortex that prevented aft wing stall and eliminated wing rock on the model.

We then did more tests with tufts to verify that, indeed, the departure is caused by aft wing stall. We then installed the cuff - initially 50 inches long, and found that it eliminated departures but did not eliminate wing rock. We then trimmed it to 38 inches long, and found, as NASA predicted, it completely eliminated wing rock and departures. Wing rock induced with the ailerons would damp out after being excited.

At aft limit cg the airplane is as safe as at forward cg. The vortex formed by the sharp edge of the cuff results in the stall angle-of-attack being raised by more than can be expected by the increased droop of the leading edge.

If you have difficulty understanding the above technical discussion, that's ok. Your airplane may already be stall resistant at the aft cg limit in general. However, flight tests and homebuilder experience indicates that it is possible that at aft cg positions, certain conditions could exist where it may be possible to stall the aft wing. A stable spin will not result, but the airplane can roll off to one side and lose considerable altitude.

The end result is that when you install the simple extension to your wing leading edges your airplane should be totally stall resistant at any allowed cg position.

Based on the results of these tests we recommend that you limit your aft cg to forward of F.S. 100.5 for short canard and 99.5 for long canard (see page 27 of your owners manual), until you have installed the leading edge cuffs. Install them exactly as shown on page 6 of this newsletter. Do not modify their shape or round their ends. If you are now building a VariEze, the cuffs can be installed any time after chapter 6. Do not change anything in chapter 6.

The cuffs have been dive tested to 215 knots to verify freedom from flutter. Data also indicate that they provide a small improvement in stability, max speed is degraded slightly - about two knots. Climb and cruise range are not changed.

Do not omit this improvement - do take advantage of the extra work we are doing to provide you with the safest possible airplane.

NEW SYSTEM SOLVES NOSEGEAR COLLAPSE - As reported in the "Canard Pusher", several EZ flyers have had their nosegear come out of the lock during taxi or landing. We had traced these to interferences which prevented full NE11 engagement, or improper rigging and snub of NE10, or to incorrect pilot actuation of the system (pushing downward, rather than forward on the knob, bending NG10). However, even though all these items have been covered in the newsletter we still find that many are still experiencing collapse. Damage is generally minimal, but in three instances it has resulted in closing an active runway and the required filing of an FAA incident report.

Being finally convinced that this would continue to be a problem, we have developed and tested a new retraction system. NG11, NG12 and NG13 parts are now obsolete and no longer available from Brock. The new system is being fabricated by Brock. The new system can be easily installed even in a completed airplane. It involves removing the bolts in the NG13 guides, removing NG11 and NG10, installing a worm-drive system in the same bolt holes previously used for NG13's. The long NG10 tube is cut down to a short pushrod. The worm is actuated by a 3/8" x .035 aluminum tube extending to a crank on the instrument panel. This gives the pilot a lot more leg room, particularly with the gear up. You will now have room for two small engine instruments in the center console. Also, the possibility of injury in a crash with the gear up, is probably reduced. For these reasons you should retrofit your completed EZ to the new system, even if you already have the old system installed.

VARIEZE EXHAUST SYSTEMS - As you probably know, Ken Brock manufactured VariEze exhaust systems early in our program. His production was halted when it was discovered that that design was cracking due to vibration - induced fatigue, even though our prototype flew approximately 100 hours with this system without problems. Since then, at least ten different configurations have been tested. Some successfully, some failed, and some do not yet have sufficient flight time to judge as successful. The two most reliable so far are shown in the second edition of Section IIA and in CP #18. Most EZ's are using one of these systems. A few EZ's are now flying with a cross-over system that results in rather large, blunt bumps on the lower cowl. As far as we know these are holding up, but the separated airflow on the

bumps more than defeats the extra power in drag, and causes high propeller noise. We do not have very much information on this system, as to the number of flight hours etc. We are also interested in learning the operational experience of the other systems now flying. For example, the one at Oshkosh that exited at the cowl T.E. split line. As soon as we can identify an additional system that: (1) is quieter than straight stacks, (2) provides at least 90 degrees F carb heat temperature rise, (3) fits the airplane without excessive drag, (4) can be produced at low cost, (5) weighs less than eight lb., and (6) has been flight tested at least 125 hours without any indication of failure, then we will arrange for it to be produced by Brock for sale to homebuilders. In the mean time we will continue to recommend either the noisy straight stacks or the expensive mufflers. The Flight Research mufflers have been on N4EZ for 17 months and 155 flight hours. They result in a five mph. penalty but are quiet and have had no indication of cracks or degradation.

Please send us any operational experience data you have available on the system you are flying. Describe the system and engine type, any failures or degradation, temperature rise of carb heat system, and number of flight hours.

ACCIDENTS. VariEze takes on Cessna 172 at the Cable Airshow, 9 January 1979 - - both lost. Gerald Gardner's VariEze was on take off roll and at rotation speed a Cessna 172 pulled out for take off right in front of him. The VariEze rotated abruptly to try to fly over him and almost made it. The EZ's left lower winglet struck the 172's right wing in the flap area, followed by the left main gear hitting the right wing tip of the 172.

The EZ struck the ground beyond the 172 in a right turn. The canard tip and nose gear hit first, folding the nose gear back.

The canard came off the airplane removing part of F22 bulkhead. The canard and elevators including lift tabs were undamaged. The left lower winglet was damaged. The wing attach fittings were not damaged. The main gear folded back, failing three glass tabs and pulling one aluminum extrusion from the fuselage. The main gear strut was not failed. The right wing trailing edge split open from the aileron to the trim tab. The right winglet failed at midspan. The Cessna's right wing was totaled. There were no injuries. Gerald had 118 hours on his EZ at the time of accident. He said he loves his galactic wonder and will rebuild it.

CAUTION - FLUTTER As you should know, control surfaces must be balanced to the proper criteria or flutter is possible. Flutter is a very dangerous thing that usually results in inflight catastrophic structural failure. In the past we have cautioned you to observe balance criteria because we thought it might flutter if unbalanced. Now we know it will. One EZ owner bought a new VariEze from a builder and took his word that all was in order. It had retrofitted wide chord elevators and an elevator trim tab. The builder had failed to rebalance the surfaces, even though he had been reminded to in the last newsletter. The new owner experienced violent flutter while flying at a moderate cruise speed. Luckily, he was able to stop it by forcing the stick aft and reducing power. There was no damage. After the flight he removed the elevators and found they balanced more than 30

degrees nose up, way out of the 10 to 20 degrees nose-heavy requirement. Had the operator followed the owners manual procedure he would have found this before flight. He is very fortunate to be alive.

Many builders have overweight elevators, and then have added the extension, finding that they need excessive balance weight. We have not flight flutter tested an excessively heavy elevator and do not plan to do so. We therefore cannot tell you whether a balanced excessively heavy elevator is safe. It may not be safe. The elevators are a very small part of your airplane, but are the most important and most critical part. Do not accept less than perfection on your elevators. They must be light so that excessive balance is not required. They must be shaped exactly to fit the templates of Newsletter 17, page 11. The adjacent photo shows a wide chord elevator built at RAF this month. It balances 17 degrees nose down without paint and

---

will balance at about 13 degrees with paint. The balance weights are positioned exactly as shown on the plans. No excess weight is required. They weigh 3.3 and 3.6 lb, with weights, ready for paint. If your elevators are overweight or are shaped wrong, strip them down to the bare aluminum tube and rebuild them. That extra work is the most important work you can do on your aircraft. Do not add more than 0.3 lb balance, to correct an overweight elevator. **PHOTO OMITTED**

VARIEZE BUILDING HINTS.
Cold weather operation hints from Nat Puffer, who has been operating his EZ in 15 degrees F (-26 degrees C) weather. "Direct a hair dryer into the air inlet for one hour before starting engine. 220 degrees F CHT and 120 degrees oil temperature resulted even when the oil tank insulator was used. I closed off half of the airscoop area and now can operate ok with 400 degrees CHT and 145 degrees oil. I must run continuous carb heat for smooth operation."

Also from Nat "modifications that add metal or tools carried in the thigh-support compartment can ruin the normally good performance of COM and NAV antennas."

John Foy, "After being unable to solve my high CHT, I calibrated the probe. At 200 degrees it was within 5 degrees. At 450 degrees it read 520 degrees! To calibrate I used a can of motor oil, heated with a propane torch. Immerse the probe and measure temp with a candy cooking thermometer. The gage was replaced and it now reads ok." More from John "Flight characteristics of our aircraft were not correct. We required a lot of nose up trim at all speeds. The faster we went, the more nose up trim was needed. Also at 20 mph before the stall the nose would come up to the point where nose down elevator would have to be applied. I believe that it was due to the strong nose up trim that was required for level flight. As the speed dropped off, the trim spring authority became the dominant factor. At the stall, back pressure was needed to keep it there and the nose would oscillate up and down, very slowly while the aircraft descended. The aircraft stalled straight ahead with no tendency to fall off on a wing. After talking with you I decided something had to be done to bring the aircraft to normal flight characteristics. We were convinced that our weighing was correct. In

your drawings you call for a minimum elevator to canard gap of .1 inches ours was .3 inches. I decided it was too large, so I closed the gap in the full T.E. up elevator position (20 degrees). Now our VariEze responds correctly." **SKETCH OMITTED**

The following sketch shows the preferred installation of the Aircraft Spruce oil separator. If you still have some oil on the cowl, cut a hole in the separator and stuff it with two "tuffy" plastic cleaning pads, (grocery store). Patch the hole with a plate of .032 aluminum pop-riveted in place and sealed with ProSeal sealant. This eliminated oil loss on N4EZ even during steep climbs, stall/spin and aerobatics. **SKETCH OMITTED**

Jim Ball reports his breather works better when tapped into the top of the starter cover plate, with an internal baffle to deflect gear train-slung oil. He plugs the normal breather.

Lee Herron contributed the following simple low-cost cabin heater. It uses a push pull control at the rollover back to a butterfly valve (made from scrap stainless) at the firewall. A two inch hose runs to a tee in the carb heat line. The heat is merely dumped in the baggage compartment. It flows around passengers' vented-type seat cushion (or it could come through holes in the seat back and forward through the rear armrests). Heat then goes over rollover (defrosting canopy), down around pilot's legs and exits around openings around nose gear. Canopy and main gear must be well sealed. Lee claims it works excellently. **SKETCH OMITTED**

CP19, Page 4

Do not peel ply entire structure. This starves epoxy from lower foam surface, makes inspection difficult, gives an erroneous impression of good surface smoothness, makes it easy to unknowingly damage structure during finishing and adds weight. Do peel ply surface edges of glass plies whenever they exist and, of course, whenever a lay up will be later made over a cured surface.

When fitting baffles, be sure to put cowling halves on one at a time, to carefully check for leaks. Metal must be within 3/4" of cowl to prevent rubber seal blow-by. A small rib on the left side attached to the cowl at the trailing edge is usually needed to seal air leakage.

Rosenhan wheels have sharp edges outside rims at three places. Round these to avoid cutting tires. Use only four-ply tires and inflate to 65 psi.

Jim Heitkotter 7327 N. Peach, Clovis Ca 93612, has offered to fly local EZ builders in his EZ to check them out before their first flight. It is a good idea to get an experienced EZ pilot to do your initial testing. Do get some EZ back seat time, if possible.

VARIEZE PLANS CHANGES.

Owners Manual
Bottom of page 34 add "are you sure you have complied with all details in appendix I?"

Section V	add "Dupont 100s can be substituted for 70s primer"
Section I page 17-5	AN4-7A should be AN4-10A (4 places). Also add "delete NG10, NG11, NG12, and NG13. Install worm gear retraction system shown in Newsletter 19"
Section I page 2-2	Revise the parts list to reflect the new nose gear system. AN4-7A (12) should be (8) AN4-10A (4) should be (8) RE4M6 (1) should be (2) AN316-6 (1) should be (2) AN3-10A (8) should be (9)
Section I page 2-1	Delete NG10, NG11 and NG13 Add, worm drive assembly - complete or individual components
Section IIA page 2 2nd Edition	0505-165 should be 0585-165 0716-202 should be 0716-020 "polyurethane" should be "nylon" (2 places). Add 3/8 x .035 2024T3 tube 70" long. 5/16 x .035 4130 tube 4" long.
Owners Manual page 27	Change aft limit cg to FS100.5 (short canard) and FS99.5 (long canard). These restrictions can be lifted after cuffs have been installed and flight tested.
Section IIA page 4	Oil Pressure gage listed as 287 AM or 287A8 should be 298A8 or 2A8. Delete 103-18 adapter.
Section I Chapter 6	add "see CP #19 for addition of stall cuffs on wing leading edges."

QUESTIONS

Q. I'm looking for a parachute for my flight testing what do you suggest?

A. We use a "security," it's only 16 lb and allows a 6'4" pilot to fit the EZ. There are other thin-line type chutes available. Check with the local soaring community. Sailplane pilots nearly always wear a chute and will generally loan you one for your testing.

Q. I have traces of black material coming from my epoxy pump, what now?

A. This is aluminum from the pump cylinder and is not a problem.

Q. My speed brake retracts at 90 mph even though the springs are tight.
A. Reduce the off-center distance of the stop for the rod end at the pushrod. It should be stopped at about 1/2" from a straight line drawn between the two pivots.

Q. My resin and hardener appears to have some settling in the bottles. Should I use it?
A. No, heat a jug of water to about 190 deg. Float the bottles in this jug for 1 hr to warm the resin. Shake the resin bottles. Then keep them stored at room temp. The settling should not reoccur.

Q. I want my EZ to look more like a Defiant. Can I eliminate the lower winglet?
A. Performance-wise, yes, it only gives about 1% induced drag reduction. But do not leave it off - it protects the rudder and cable in case you drag a wingtip on takeoff on landing.

DISTRIBUTORS

FRED JIRAN - recent reduced availability of components is now resolved. Normal 8-week delivery of landing gear is actually much shorter. Fuel tank orders received by 28 Feb. will be shipped by 31 Mar.

THE AIRPLANE FACTORY, Dayton, now offers 1/2 price replacement for canopy breakage within 3 years.

NEW PROP - Proton Manuf. Co., 5595 W. Colorado Pl., Lakewood Co., 80226, (303) 936-1683, makes a VariEze prop for the 0-200. Our evaluation shows it to be well built and has good takeoff, climb, and noise level. Maximum speed is about 5 kt slower than the Ted Hendrickson prop.

FOR SALE VariEze N1WX Dragon, by Lee Herron - Designers' Award, Oshkosh 77. See "Sport Aviation," Oct 77 and "Air Progress, Apr 78. 200 Hr TT. Pants, solar cells, mufflers, all mods. Box 357-WOB, West Orange, NJ. 07052 (201) 736-9092 Lee and Dianne are now building a Quickie.

A75-8 TT 1157 hr, T.S.O. 268 hr, all logs (206) 455-5365 after 5.

C-85 engine new major. D. Straley, 488 Fairfield, Gretna, La. 70053.

New 0-200A Cont. in factory crates in storage from sky scooter program, $4,500 outright. Adams, 234 N. Juanita Ave., Los Angeles, Ca 90004 (213) 487-2018.

A-75 engine 100 SMOH, Jim Banks (209) 734-7809, see at Del Air, Strathmore, Ca.

Lyc 0-235-C, 947 TT logs, $1300 torn down or $2500 overhauled. Hal Dunning, Bx 5606, Kirtland AFB, N.M. 87185 (505) 247-8591

VARIVIGGEN NEWS - by Mike Melvill

N27MS has flown approx 30 hrs since the last newsletter and is performing flawlessly. Very few builders responded to our request for information on VariViggens; come on guys. How about a first flight report from those of you who are flying? For that matter, we would really like to know how many VariViggens are flying.

I have heard from a couple of builders; Ken Winter has his upside down, and the sides and bottom are skinned and he is applying Dacron. Orville Winfield, and Charles Allen are both building the same main gear retract system as in N27MS, and both report good results so far. Orville has completed his, but not installed it yet, and it looks excellent. Incidentally my system has worked perfectly for 1-1/2 years, 260 hrs and over 320 landings, with no maintenance. While on the subject of the main gear system in my Viggen N27MS, which is now incorporated as the standard system in the new edition of the VariViggen plans, here are a couple of corrections to the parts list and drawings as supplied to those of you who have acquired the drawings for the new gear system from me.

The parts list calls out 4 KP6A bearings,; this should be 6 KP6A bearings. Add 2 pcs drill rod 5/16 dia x 4-3/16 long to the material list. On drawing #3, spacer WDG4 should be .340 not .250.

Aircraft Spruce & Specialty are now able to supply all parts reqd for the new main gear retract system. These are not premachined parts, some, such as the CD1145 worm gear will require machining.

The 12" dia spinner (long) available from Rattray, works well on the VariViggen, as it clears the starter better than a 13 or 13-3/4 spinner such as one from a Grumman Tiger.

Talked to Jesse Wright, the Viggen builder who supplies precut canard, inboard wing, fuselage bulkhead, and vertical tail kits. I had not seen one of Jessie's kits before and I must say I was impressed with the quality. If I was to do my Viggen project over, I would go with Jessie's kits, just for the time it would save. He also includes a very complete and helpful pamphlet.

Now, for "CP" 20, how about some progress reports? Also, we must try to have at least a couple of Viggens at Oshkosh 79.

INSTALLATION OF WING CUFFS - Refer to the sketches. The cuffs are a cambered leading-edge extension to the wing airfoil. If this is a retrofit, sand the paint off until patches of fiberglass begin to appear. We did not remove the wings to install the cuffs, but it is more convenient to do so. Nail the templates to the foam block and cut one L/H and one R/H cuff. Bond the foam piece to the wing with wet micro. Be sure the waterline is level and the cuff is pulled tightly onto the wing for cure. After cure, carefully remove the excess strips of foam and smoothly contour the shape back over the wing. The surface should not be lumpy or wavy (see "CP" 16, page 4). Glass with 1 ply BID at 45 degrees lapping 1" onto wing skin and peel-ply edges. After cure, apply featherfill or dry micro and sand entire cuff to a smooth contour. Use 1 ply BID and flox corners to cover bare foam at the ends.

SKETCHES AND PHOTO OMITTED

INSTALLATION & OPERATION OF WORM-DRIVE NOSEGEAR - The sketches below show the operation of the system. The NG50 arms travel 156 degrees, striking the NG14 spacers at each end of travel. It is over-center in the down position, thus, landing loads are not applied to the worm gear. The pilot's crank uses 10.8 turns for full travel, taking five to seven seconds. Previously you had to slow to 100 mph to extend the gear. You can now extend it at 140 mph, however, the crank is hard to turn above 130. When we first installed this system, we used it to lower the nose with the pilot in the airplane. This was successful until one time when the crank slipped, turned fast, then caught. The inertial loads failed the cast iron worm gear. It is possible that "cranking down" on the ground would be acceptable with the steel gear shown, but this is not recommended.

Use the plans chapter 17 procedure for installing the NG30 bulkheads - The NG14 spacers are the same. If your NG13's are installed, pop them out and bolt in the worm drive assembly. Check the assembly for freedom from binding before installation. It does not have to spin freely, just not bind up enough to make the crank hard to turn. If it binds, loosen the NG57 blocks and shim as required. The NG53 and NG58 gears must be accurately positioned to avoid binding. Use a gear lubricant on NG53 and NG60. Note that four AN960-516 washers are used to position NG58. One at the rollpin end and three at the other end. NG67 is a phenolic block with a 21/64" hole drilled at a 20 degrees angle. It is fastened to the instrument panel with two #8 screws. Install the crank and tube drilling the hole for the AN3-6A bolt with the crank in the best position to not block an instrument. Now, install the pushrod and adjust its length so the gear is pulled snug up just as NG50 strikes the aft NG14. Extend the gear and accept the down position. If everything is installed properly the pivot for the nosewheel fork will be vertical or canted bottom-forward slightly.

If you want to install a gear warning, mount the microswitch so it is engaged by NG50 or NG9 in its last ?/16" travel.

If you want to mount small instruments in the center piece, back-mount them. Make the hole in the panel 1.8" diameter maximum to leave sufficient panel stiffness.

NOSEGEAR WORM DRIVE PARTS LIST

No Reqd.	Part No.	Material
2	NG50	.125 4130N steel
2	NG51	.250 2024T3 alum
1	NG52	5/8 O.D. x .095 x 3" long 4130N tube
1	NG53	Boston gear CD1145-machining is required
2	NG54	Boston bushing FB1012-4
1	NG55	3/4" O.D. x .058 wall x 5/16" long 4130N tube

1	NG56	.125 2024T3 alum 2" O.D. x 1 1/4" I.D. x .125 thick
2	NG57	1/2" x 1/2" x 1" 2024T3 alum bar
1	NG58	Boston worm HDVH
1	NG59	MS20271B8 universal
1	NG60	5/16" O.D. drill rod 3 1/4' long
1	NG61	3/8"O.D. x .035 wall x 18" long, 2024T3
2	NG62	1/2" O.D. x 1/4" I.D. x .250 long 2024T3 alum
1	NG63	375 O.D. x 5/16" I.D. x 1/2" long 4130N steel sleeve
1	NG64	.062 4130N steel crank
1	NG65	5/16" O.D. x .035 wall x 2-1/8" long 4130N tube
1	NG66	Macrome wood bead handle
1	NG67	Phenolic block 1/4" x 1" x 1 1/2"
1	NG68	1/4" O.D. x .028 wall x 3/4" long 4130N steel tube

SKETCH OMITTED

NEW EPOXY REDUCES SENSITIVITY
We have been testing a new epoxy system that is a new development by Applied Plastics. It is formulated from completely different materials, resulting in a toxicity rating of SPI0, rather than SPI2 of normal epoxies. It promises to result in dramatically reducing the incidence of epoxy allergy. Also, its peel strength, exotherm, and water absorption is improved from RAE. In order to determine its actual toxicity under the conditions of VariEze construction, Applied Plastics plans to send samples of the new material to selected homebuilders who have experienced predictable rash when using the normal epoxy. If you have a sensitivity problem that prevents you from using RAE, send us a short letter, describing your symptoms, willingness to try the new system, and to report on its results. We will select a dozen individuals and provide them with samples to try.

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, & AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY.
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.
AIRCRAFT SPRUCE & SPECIALTY CO, 201 W. Truslow, Box 424, Fullerton, Ca 92632 (714) 870-7551
VariViggen spruce kit, plywood kit, hardware, aluminum and fiberglass. Catalog cost $3

KEN BROCK MFG. 11852 Western Ave, Stanton, Ca 90680 (714) 898-4366
VariViggen prefabricated components: all machined parts. Catalog costs $2

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave, Dayton, Ohio 45424
VariViggen plexiglass canopy. (513) 845 9872

MONNETT EXPERIMENTAL AIRCRAFT, INC., 955 Grace St, Elgin, Il 60120 (312) 741-2223
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City Mi 48706
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS, 4102 Twining, Riverside, Ca 92509
VariViggen welded nose & main landing gear, 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, CO 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost description of car-top wind tunnel, 8"x10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air mail- overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail- overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues starting with CP#19 are mandatory for those with VariViggens under construction. Identifies new material sources as they become known. Published quarterly. Price - $4.75 per year first class mail, $6.50 air mail overseas. Back issues, $1.00 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the past several years. It covers the entire airplane, including the engine installation, fuel system, and not only covers the original standard wing in both aluminum and foam and fiberglass composite, but it also includes the composite S.P. Wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio-controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65-cu inch size. 555-sq inch wing area.

All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines). Price - $4.75 first class mail, $5.50 air mail overseas.

CP19, Page 10

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $2600 (less engine) in about 1000 man-hours, or from prefab parts and materials, costing approximately $4000 in about 600 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect and repair. The VariEze uses the small four-cylinder Continental aircraft engines. The 0-235 Lycoming, stripped of starter and alternator, is now being tested and should be available soon. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 20 gallons of fuel. Frontseat passengers up to 6', 7"/250 lbs and backseat passengers up to 6', 5"/220 lbs can be accommodated plus a modest amount of baggage in two custom suitcases. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (60 kt/70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin

and dive tests to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

THE HOMEBUILDER SUPPORT The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher," published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound, 11"x17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION IIA - Continental A65, A75, C85, C90, 0-200

SECTION IIC - LYCOMING 0235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operational handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 20. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 20. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 20. If you are building a VariEze from the 2nd Edition plans you must have newsletter 16 through 20. A current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 9:00 to 12:00 and 2:00 to 5:00 on Wednesday through Saturday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions" This will speed our reply.

RAF ACTIVITY since the January Newsletter has included construction of a new EZ, builder support, development work on the Defiant, and extensive flying of our Defiant, VariEze and VariViggen for airshow practice. We have flown a three-aircraft airshow demo each Saturday at Mojave for the last several months. The new EZ under construction (N79RA) should fly by mid May. It will be powered by a Lycoming 0-235. It will be the test aircraft to flight-test the Jiran prefab wings.

The adjacent photos show the RAF crew, so you can become better acquainted with those who you may only know as a voice on the phone. Sally and Mike Melvill, builders of N27MS, the award-winning VariViggen have been with us since October. Both are excellent pilots as well as airplane builders. Their experience in building both a VariViggen and an EZ and in understanding the needs and problems of the homebuilder, is a most important asset to RAF. Also pictured are Dick and brother

Burt Rutan. Dick joined RAF a year ago after a 20 year hitch as a USAF Fighter Pilot. **PHOTOS OMITTED**

CP20, Page 1

CONGRATULATIONS! to the following who have made VariEze first flights since the last newsletter:

Dan Lee	California
Darl Hess	Florida
George Dirks	New Mexico
Jim Ball	Missouri
Gary Johnson	Texas
Mr. Griswald	Arizona
Ray Cullen	Oregon
Carl Gearhart	Penns
Brian Giesier	Colorado

There are probably more, but these are all we're aware of. Be sure to give us a report when you fly. This is very important to us so we can best support others. In particular, if you have had any problems or have found any improvements that would aid other builders, be sure to let us know so we can pass them on in the Canard Pusher.

THE AD-1 was delivered to NASA's Dryden test center last month and immediately began taxi tests. It is now being instrumented with a data system and should be flown in June. The AD-1 started as an unsolicited proposal by RAF to NASA in December '75. RAF did the detailed design between May 76 and Feb 77 under a $12,000 contract. AIC, of Long Island N.Y., won the construction contract and started construction in December 77. They delivered the flight-ready aircraft, including a static load test, in February 79 for a total contract cost of $239,000. Until recently, the aircraft industry did not believe it was possible to design and build a manned, skew-wing, twin-jet research aircraft for less than several million dollars. It is interesting to note that the total work done by RAF and AIC was done at a profit and at far less cost to the taxpayer than the NASA tasks of overseeing the contractors and doing a simulation! While we expect the AD-1 to provide the basic subsonic skew-wing stability data it was built to provide, we expect its major impact will be that it is possible for the government research agencies to procure a truly low-cost aircraft, working with a small contractor and employing the moldless composite construction similar to the VariEze.

DEFIANT We have decided to proceed with a type-certification program on a light twin based on the Defiant prototype. It's cabin design is completely different from the prototype. It has a clamshell door with roomy seating and baggage for five adults. Specifics on its configuration, performance, etc will not be released until it is in flight test in late 1980. Certification is anticipated in late 81 or early 82. Meanwhile, we continue to gather operational data on the Defiant prototype, N78RA. Last week it flew nonstop from Mojave to Wichita (1265mi) at 17,500 ft, at 175 knots, burning only 5.4 gal per hour per engine, landing with 1 1/2 hour fuel on board. It is being evaluated in the IFR environment, including approaches at minimums, a zero-zero takeoff (actual IMC), and light ice on four occasions. It

has seen 270 hours of very vigorous testing of all types including aerobatics and spin-attempts, and has yet to cut a flight short due to a precaution of any kind. Due to the fact that we are doing this program with very few people and very low overhead, we will not have time to respond to questions, etc on the Defiant for the next two years. We plan to be very low key on release of any information or promotion of any type. This newsletter will report any releasable progress as we proceed. If you do want an advance look at the Defiant's capabilities and are interested in beautifully-done sound film, send a SASE to Ferde Grofe, 18139 Coastline Dr. Malibu, Ca 90265. for his flyer on the new film "Defiant".

JIRAN'S PREFAB WINGS - STATIC TEST Burt, Dick and Mike were present when Fred Jiran static loaded his VariEze prefab wings and centersection. NASA was also there, and had installed 24 strain gauges all over the wings and centersection spar. The wings were loaded to the design limit of 7.5 gs with no problem whatsoever. In fact, due to a calculation mistake we had earlier loaded them to 8.25 gs and almost twice the expected torsional loads. The strain gauges verified adequate stress margins at all measured locations. We will begin a thorough flight test program on these wings and center section (the same ones that were used for the static proof loading) here at RAF next month. Look for a full report in CP #21.

CAUTION - OVERWEIGHT! It has come to our attention. that some VariEze builders are operating their VariEze's in an overweight condition. This is a high risk activity and an extremely hazardous practice.

Every VariEze builder should know, the maximum gross weight is 1050 lbs. Under certain restricted conditions this can be raised to 1110 lbs for takeoff only - (see CP #14, page 5). Attempting to operate above these weights and/or using higher than recommended horsepower, definitely raises your risk above an acceptable level.

Takeoff's, landings, off-field landings, maneuvering, or flight in strong gust conditions may result in an accident that could destroy your aircraft. Never operate above the recommended gross weight. An accident can compromise the freedoms of all homebuilders. Please do not let it happen.

VE STALLS Dan Lee, of Livermore, Ca has installed wing cuffs per CP #19. Prior to cuff installation Dan had on four occasions experienced divergent wing rock, resulting in departures and spiral recovery rolling dives. (CP #19). His post-cuff installation flight report follows: "I did not get a stall with or without power, only a slightly perceptible wing rock, power off at full aft stick. The overall effect on slow speed flight control is great, as is the improvement in confidence and peace of mind". Do install the cuffs exactly as shown in CP #19.

VE EXHAUSTS There are now at least four VariEze's with over 300 hours, two of these are 0-235 Lycoming's one of which has standard exhausts as per Section IIC with no problems. 0-200 Continentals, have not been so fortunate. The muffler system though heavy works very well, at this point we have removed it and consider it to be a proven exhaust system. In its place on N4EZ we recently installed an exhaust system designed and built by VariEze builder Herb Sanders of Memphis. This is the

exhaust that exits out of the trailing edge of the cowling. We only have 25 hours on it so far and Herb has 70 hours on his, so it is too early to be certain, but so far it looks good. It is not as quiet as the muffler system, but is half the weight, and simplifies cowling removal. We shall have to wait until we have 150 hours or so on the system before we categorically recommend it, but the concept and workmanship is good.

The cross-over system is structurally sound and does increase power. However it cannot be adequately faired on a VariEze to prevent massive airflow separation in the aft closure. This causes high prop noise and a 15 knot speed penalty.

We will be testing an entirely new system on our new EZ.

CLARIFICATION - VARIEZE ENGINE WEIGHT
240 lbs is mentioned as a maximum weight of engine, prop, prop extension, exhausts and spinner in Section II. This weight is the maximum allowable vibrating mass and does not include engine mount or cowling. Maximum engine and accessory weight is 215 lb.

WIDE CHORD ELEVATOR - STABILITY AND STALLS Many builders have been confused about the various aerodynamic effects of shortening the canard and widening the elevator. The reason for the confusion is that the effects are not what one would immediately think. Hopefully the following discussion will clear the air:

Question - the wide chord elevator is bigger and thus gives more effect per degree - why doesn't this make the controls more sensitive?
Answer - sensitivity is more a function of effect per stick force, not displacement. True, the wide chord increases effect per degree by about 12%, but the distance from the elevator's center-of -pressure to its pivot is twice as far, thus stick force per effect is nearly doubled.

Question - I understand why shortening the canard moved my airplane center of pressure (and cg range) back 1.2 inches due to less area on front. But, why didn't the cp move back forward, when I installed the wide-chord elevator, thus increasing canard area?
Answer - The wide chord elevator has a negligible effect on aircraft static stability for two reasons, (1) the elevator "floats" when angle of attack changes. Thus it's area has much less effect on stability than the fixed canard area. (2) The wide chord elevator results in less, not more, aspect ratio, as compared to the area added by increasing canard span.

Question - Since the wide-chord elevator has more aerodynamic power, it should be able to drive the airplane into a deeper stall, correct?
Answer - No, the airplane's maximum angle-of-attack is limited by the stall angle of canard airfoil. Adding more elevator can get it to stall with less elevator position, but it will still stall at the same angle, and still limit the aircraft to a safe attitude without stalling the aft wing. Note that even though a large elevator can increase the maximum lift coefficient of the canard, larger elevators actually

decrease the stall angle and thus cannot increase the angle seen by the aft wing. The aft wing angle is the main factor for stall characteristics.

LANDING GEAR There have been two reported main gear failures, in which we suspect 'creep', since these occurred on overweight airplanes in hot temperatures. The failure was on top of the main gear strut between the mounting tabs, and showed up as a wrinkling or buckling of the BID wrap. This may have been aggravated by not "setting" the gear (ref. CP #18 page 5). Main gear "creep" will also show up as a slow long-term reduction of wheel camber or increase of gear spread (distance between wheels). We now recommend the following:

1) Be sure to 'set' your gear after every flight.

2) Inspect the top of the main gear strut, between the tabs, through the hole in rear seat bulkhead occasionally.

3) For new VariEzes under construction. Sand the entire gear strut dull and lay it trailing-edge down. Using RAEF, lay up three plies of UND spanwise from axle to axle, draping each ply from trailing edge over the leading edge to trailing edge. Be sure fibers are straight. After cure, sand trailing edge smooth and apply the two plies of BID, one from the leading edge and one from the trailing-edge, per CP #15 page 6. Before laying up the attach tabs per CP #14 page 6. These three plies per side of UND will stiffen your gear about 15%.
SKETCHES OMITTED

4) If wrinkles, or loss of camber, or spread is noted in operation, remove the main gear strut, remove wheels, axles and brake lines. Strip off the tabs and thoroughly sand the entire strut. You may see evidence of compression fractures on the top surface of the gear. These can be repaired as follows: Lay up seven plies of UND, three plies from axle to axle (per #3 above) and the remaining four plies lay up 4" shorter on each side progressively, (see sketch). Then apply the BID and tabs, per #3 above. **SKETCH OMITTED**

EPOXY Applied Plastics has sent out about 20 samples of the new low toxicity epoxy, but it is too early for us to have received any reports. We have used it here at RAF on our new EZ. If we receive positive results on the toxicity tests and the system passes all structural and workability tests, it will replace the current RAE systems.

While we are on the subject of epoxies, I would like to remind you to be as accurate as you can when using your ratio balance. Make sure the pivots are clean and work freely. Mixing epoxy requires far more accuracy than mixing polyester (boat resin). If you think of your resin as a bunch of "threaded bolts" and of your hardener as a bunch of "nuts", you will see that only with a perfectly accurate mix do you have one "nut" for each "bolt". Only the molecules "bolted together" as it were, do any good. So the greater accuracy you use to ratio your resin-hardener, the stronger your epoxy (and VariEze) will be.
SKETCH OF SCALE FOR NON TOXIC EPOXY SYSTEM OMITTED

CONTROL SYSTEM ROD-ENDS The VariEze control system is unusual in that it uses the small HM-3 rod-ends in its primary controls. Aircraft normally use the 1/4" hole HM-4 as the minimum size. Justification for this is that the control surfaces are small, sized for the low forces required for a sidestick control. Thus, the design safety factors are still larger than in normal control systems. However, the small HM-3 rod-ends are relatively fragile if they are subjected to bending or twisting loads. These loads do not exist in operation, but they can occur when the canard is being removed, or at the stick if the roll stops are not adjusted correctly. We recently heard from a builder who broke an HM-3 while he was installing his controls! This is a very serious concern, since there is no redundancy in the pitch system to save the airplane if one should fail in-flight. This is not as serious in the roll system, since the airplane can be steered with rudder or the other aileron. Due to the relative frailty of these rod-ends, we are recommending that you immediately replace the four primary pitch rod-ends with HM-4's as shown in the adjacent drawings. This includes both ends of the CS136 tube and both ends of the CS102 tube. Note that two CS201 spacers are required for each rod-end on the CS102 pushrod to allow sufficient roll travel. They are steel, 5/16 OD x 1/4 ID x 0.1 long. Also, the two CS111 spacers are replaced by CS202 spacers. Four of the CS1 inserts now are CS1A (1/4" x 28 thread). Note that this change also effects the parts list on several bolts, washers and nuts. Drawings for CS1A, CS201 and CS202 have been supplied to Brock so he can manufacture them. Aircraft Spruce and Wicks have all the new hardware in stock. If you are retrofitting you can drill (#3 drill) the CS1 spacers and tap 1/4 x 28 thread. **SKETCHES OMITTED**

VARIEZE PLANS CHANGES

Section I pg 18-1 — add "see CP #20 for installation of three plies UND on strut before the BID wrap"

Section I chap 19 — add "pitch system rod-ends from the elevators to the front stick (four total) have been changed to HM-4 size. See CP#20 for details".

Section I pg 2-1 & 2-2 — Revise the bill of materials as follows to reflect changes required to change to the HM-4 rod-ends.

Subtract

BUILDERS HINTS When you cut BID or UND, mark the cloth where it will cross the center line with a fine felt marker. This mark can be very helpful in perfectly aligning such lay ups as canard spar caps, etc.

Draw lines (broad felt tip marker) on your glass cut-out table at 45 degrees to the sides on 6" centers. This is a big help when cutting BID.

Be careful when storing foam blocks, not only can sunlight ruin it but rats and mice love to dig tunnels in it!

Finding fuel tank leaks. Purchase a can of Freon from your friendly auto air conditioner repair man, and borrow his Halogen gas sniffer. (This may require some persuasion!). Squirt some Freon into the offending tank, replace the cap, and pressurize the tank, (blow into the vent). Use the sniffer to locate the leak or leaks, mark them carefully and repair per CP #14 pg 10. This method will find even the tiniest pin hole leaks.

Check your maingear toe-in. This can really effect the life of main tires. See the accompanying sketch, and clamp or hold one 36" long straight edge on the outside of each main wheel, be sure it touches the rim both fore and aft of the axle. Position of the straight edges fore and aft is not important, as long as they are the same. Measure accurately the distance between the ends of the straight edges at 'A' and at 'B'. For 1/2 degree to 1/4 degree of toe-in per wheel A-B=0.3" to 0.7". **SKETCH OMITTED**

An excellent cowling idea from Herb Sanders - Instead of gluing your cowling rib to the bottom cowl, glue it to the main wing root. This allows you to better fair the cowling in with the wings, and makes it simpler to remove the cowl, as either the bottom or top cowl can be removed independently of each other without hitting rudder cable or aileron tube. This requires four more camlocs (or screws) on each side in the bottom cowl. The only time this would not be convenient would be for the builder who intends to trailer his EZ to and from the airport, requiring frequent wing removal. We have modified N4EZ to this configuration to test the Jiran kevlar cowl and are very pleased with it.

Jim Eggleston wired up his instrument panel before installing it in the fuselage. He then bound all the wiring into a harness, color coding the wires and tagging each wire. The harness was then removed and the panel installed. See photo.

Jim also reports that he used dead soft .016 aluminum, called handyman's metal, obtainable at the hardware department of Montgomery Ward's in rolls, to make his hotwire templates. This material can be cut to size (after paper templates are glued on) with ordinary scissors.

Before floxing VECS3 hinges into your canard, bondo small wood blocks adjacent to the VECS3's and overhanging the slots cut in the canard. VECS3's can now be clamped to these blocks, templates can be removed from under the elevators, and the elevator travel can be checked before final potting in flox. Leave clamped until set. This tip from Minnesota's EAA Chapter 587. **SKETCHES OMITTED**

When countersinking difficult to reach holes, e.g. 3/16" dia holes in engine mount extrusions, a 9" long piece of 5.16" dia x .035 wall aluminum tube can be used. Drill and tap a 1/4 x 28 thread in one end and screw in a 100 degree countersink with a 3/16" pilot. **SKETCH OMITTED**

Many builders have requested a summary of weights of each individual part. These are weights of the parts before any finishing.

Complete wing/winglet aileron assembly	43 lb	
Above, after finishing	46 lb	
Winglet before cutout for rudder	2.6 lb	
Canard (142")	16.5 lb	
Elevator (left)	3.6 lb	with balance weights
Elevator (right)	3.3 lb	with balance weights
Wings (each)	34.0 lb	
Ailerons	3.5 lb	
Center Section Spar	21.0 lb	
Fuselage (at end of chap. #12)	65.0 lb	including C/S spar
Canopy (end of chap #22)	14.5 lb	

When cutting out small BID circles, as in bolt hole reinforcement in NG30's, fold up BID cloth strips to required number of plies (30) and clamp between two scrap pieces of 1/4" plywood (firewall material). Vice grips work best. Now cut through plywood and glass with fine tooth coping saw or band saw. Presto perfect circles of BID!

Gear and canopy warning - this system has a resetting defeat feature. The main advantage is the ability to silence the horn, while doing gear-up, slow flight or descents. The light stays on as long as the throttle is retarded. Each time you cycle the throttle the horn will sound and will have to be re-silenced. This eliminates the possibility of switching the warning system off during gear-up descents, and forgetting to rearm it for the landing approach.

Side consoles and control system installation - a simpler way. The adjacent photos show how we did it on N79RA. Note how only the forward three inches of the aft console is installed. After controls are installed the remainder of the console will then be permanently

installed. Note how large cutouts are removed from the forward console to get access to the stick and forward belcrank. After controls and trim springs are installed we will fabricate a three ply glass removable cover over the stick area. **SKETCHES OMITTED**

SKETCH OF JIM EGGLESTON'S INSTRUMENT PANEL OMITTED

PVC FOAM COLORS
Several builders have accidentally used 9mm PVC foam for their F22, F28 and instrument panel bulkheads. The confusion has arisen through variations in color of the PVC foam. Rather than going by color check the thickness and obvious density. The 5mm(.2") high density foam is more dense than the 9mm (3/8"). It has a smoother texture - finer cells than the 9mm, which has a course texture with a larger cell structure. If you are one of the builders who has made this mistake, here is the fix. The only area that is a structural problem, is F22 where the canard lift tabs are attached. To stiffen this area you should dig out the foam as shown (use a 1/4" drill) and make four (4) 1/4" birch plywood inserts (scrap firewall material), which should be a nice snug fit, and should be glued in with wet flox. This mistake will, of course, also necessitate longer VECN1 bushings. This fix will provide adequate bearing strength, and structurally the airplane will be more than satisfactory. **SKETCHES OMITTED**

SHOPPING
D and J Coats have come up with a really fine VariEze belt buckle, see photo. It comes in a brushed or polished finish. Orders can be turned around in three to five days from receipt of order. **PHOTO OMITTED**

Taos, N.M. 87571

Radio Shack has a 12v warning horn suitable for gear/canopy warning. Model #273-051 for $1.89

Calectro, G.C. Electronics, of Rockford Illinois 61101, has a mini meter # D1-941 in the 0-500 ma range for $10. that measures 1 1/8" square, and is good for measuring power output of your solar cell.

Bud Gross, an E-Z builder has designed and built expressly for a VariEze, a really good looking trailer. He will send you a flyer with pictures for $1.00 and SASE, or you may order construction drawings for $20.00.

Arroyo Grande, Ca 93420

ROTORWAY RW-100 ENGINE IN VARIEZE - Our earlier plans to test this engine this spring in N4EZ have been postponed. Several items must be improved by the engine's manufacturer before it will be acceptable for us to begin the installation test: Currently, the installed weight of this engine, including the accessories required for it to operate is above the maximum allowable weight for the VariEze. The engine needs an alternator because of its electric fuel pump requirement and a starter since it cannot be hand-propped. It currently has no provisions for alternator or mechanical fuel pump, yet needs 3 psi fuel

pressure. The current configuration at 92 BHP and greater than 240 lb (installed) is marginal for a VariEze.

We are, of course, hopeful that this or any new engine will become available to supplement the availability of Continental and Lycomings. We are working very closely with Rotorway and will do our best to support and assist in its successful development. When Rotorway prepares a configuration that we consider acceptable for the VariEze, we will immediately begin an aggressive flight test program with it in N4EZ to develop the information necessary to make a determination on its acceptability and to prepare an appropriate Section II.

However, our ethics require us to caution our builders to beware of any new product until it has been adequately developed and tested.

CP20, Page 6

WANTED

85hp Continental C85-12F
Earnest Deel
3710 Maple,
Warren, Mi 48091
(313) 756-3794

Continental C-90-8F with 0-200 cam - 100 hp. '0' since major. No provision for mounting starter or alternator, very light $3,100.00. Call (904) 878-5858

Michael P. Fisher, has brand new Continental 0-200 as well as remanufactured 0-200 engines for sale at reasonable prices. Write him at

8800 Coventry Drive.
Sturtevant, Wi 53177

A lot builders have reported excessive costs for engines. It seems most insist on a 0 since major engine. Why not use a half run out engine? It runs cooler than a new overhaul and can give years of operation before next major. Both our VariViggen and VariEze prototypes N27VV and N4EZ started life with 1300 hour SMOH engines. We just now bought an 0-235 Lycoming for our new EZ for only $1500. It has 1350 hours and was removed from a Yankee for installation of an 0320. We expect to get a full 700 hours before overhaul, a bargain for $1500!

ACCIDENTS since the January newsletter there have been two VariEze accidents.

The first accident was in Michigan, when a VariEze was attempting to land. It was slow on final, developed an excessive sink rate, hit hard then cartwheeled while bouncing about 30 feet into the air, and coming to rest inverted in a snow bank. Other than a small abrasion on one knee the pilot was not hurt. The EZ was substantially damaged. The pilot had 2.5 hours in his VariEze, all operating from a large airport. He had not flown in the previous three weeks due to bad weather. On this flight he was attempting to land on a 2850 ft runway with power lines and trees on both ends in a 10 knot cross wind. The runway was covered with snow except for a 45 ft wide path in the center and there were 3.5 foot high snow banks on each side. Ground witnesses reported the pilot attempted two landings but got slow on each and went around. On the third approach he once again got real slow in a nose high (estimate 30 degrees) attitude, developed heavy wing rock, and a high sink rate. He hit hard, spread the main gear strut straight out and then caught the snowbank and cartwheeled.

The second accident occurred March 7th. Just after take off from the Tims Airport, Austin, Tx. The take off and initial climb to a few hundred feet were observed to be normal, then the aircraft appeared to lose control, descending in a very steep angle and crashed about three miles from the airport. Both occupants died instantly. The aircraft had over 80 hours flying time. It had been tested extensively and had never demonstrated any unusual flight characteristics, according to the previous owner. Working with the FAA investigator, we found no indication of structural failure, control disconnect or engine failure. An examination of the canopy locking system revealed that the canopy was not locked at impact. The aircraft was equipped with the canopy safety latch and its damage showed the canopy was open approx. 1 1/2" and engaged in the safety latch at impact. There was no canopy unlatched (light/horn) warning system nor inside canopy closing handle installed. The aircraft was within the allowable gross weight and slightly aft of the aft cg limit.

The pilot had just recently purchased the aircraft a few days before in Alabama. He had a total of about 10 hours in the VariEze, mostly cross country time. According to the previous owner the pilot experienced considerable difficulty checking out in the VariEze, even though he had several thousand hours time and was Lear rated. Before the pilot left Alabama, the previous owner had made it clear that he was marginally qualified in the aircraft and should improve his proficiency before carrying passengers.

Since the canopy was unlocked at impact it would indicate the pilot had failed to complete his take off check list and took off with an unlocked canopy. It appears that the distraction of the canopy opening against the safety latch, combined with a possible panic stricken passenger (it was the passenger's very first airplane ride) might have caused the pilot to lose control of the aircraft.

There are three other documented cases of VariEze canopies opening in flight. All three were able to control the airplanes to a landing, even though they were holding it down with fingers outside the canopy frame (two inches open). With canopy open (2") in the safety latch,

other than a moderate wind blast, VariEzes can be controlled and landed normally. The following is a first-hand account of such an incident by Les Faus. "Burt asked me for few words about how it is to fly a VariEze with the canopy open. Mine opened at about 50 ft and 100 mph. I fortunately had a back seat passenger that I could rely on. Between the two of us we were able to close the canopy without too much trouble. With the canopy full open, the plane tends to pitch up and to the right. I put the stick into the left front corner and eased back and just held it straight until we could ascertain the damage. The back seat passenger held the canopy closed while we flew 15 miles to another larger airport for landing. The airplane flies well with the canopy being held with your hand around the frame. About 2" open. At that time there was no safety lock on mine. The only damage to the canopy was the center arrow stock broken by the back seat passenger trying to close the canopy. If this happens to any of you, don't panic. The airplane in controllable and can be saved. It sure gets the hair up the back of your neck at the time though!!"

Note: In 1977, Peter Krauss had a similar opening on take off while flying solo and he held it down and landed while using his right hand for control and throttle.

Any kind of accident is unfortunate. It would be even more so, if we did not try to find out why and try to prevent it from happening again. Possibly both of these could have been prevented if the pilots had carefully followed the procedures in the owners manual and newsletters, especially in the area of initial flight testing and pilot proficiency. We urgently request that the guide lines established in the operations of this aircraft be followed. Review them, be sure the warning systems are installed and operational. Follow the owners manual to the letter.

To review an Air Force adage on how to handle any emergency.

1. Maintain Aircraft Control
2. Analyze the situation
3. Maintain Aircraft Control
4. Take proper action.
5. Maintain Aircraft Control

Many have crashed light aircraft due to doors coming open, even though the airplanes fly acceptably well with the open door.

Be aware of your proficiency and the capabilities of your aircraft and don't stretch either one. Never operate at the edge of any limitation unless you need to and your proficiency is excellent. This applies to everything - weight cg, red line speed, approach speed, airport size, allowable g - etc. Limits are just that - Airplane limitations. Flight near the limitations normally require more pilot skill on any aircraft, particularly high-performance ones.

CANOPY SAFETY PHILOSOPHY There aren't many things on the VariEze that a pilot can forget that will hurt him. Failure to extend the gear prior to landing will only cause superficial aircraft damage. But forgetting to lock the canopy can be a very serious problem. I see some EZ's flying without the safety latch or a warning system and ask,

why? The response is "I am a good pilot, I always use a check list and would never forget it". Let me categorically state that no matter how good or conscientious you may think you are there will develop a set of circumstances that will lead into an error of omission.

All of us here at RAF have, at least once, taken off without locking the canopy. Each time it happened was when the "normal" procedure was interrupted by something abnormal, such as a change in runway, followed by an immediate takeoff clearance. This can and eventually will, happen to you. Having separate, redundant latches that you have to close, will not protect you. You need the catch and warning to protect you when you forget.

Some of you have found that the stainless steel SC1 catch (CP #17 pg 6 is difficult to carve out. We have released a drawing of it to Brock, so he can have them punched out and should have them available for sale.

We have seen several cases of EZ's getting too slow on final, rounding out too high and landing hard. In one case this was attributed to an error of 30 mph in the airspeed indicator. This will not happen if you fly by attitude. If you cannot see the horizon over the canard you are getting far too slow - go around and try again. One good technique is to fly final at a speed that puts the canard three to five degrees below the horizon. You should always be able to see the runway over the nose, then start the flare and fly it down to the runway in a controlled rate of sink to touch down, without ever flaring the canard above the horizon. This will give the shortest distance, since an extended over-flare will use up a lot of runway.

Remember, if you sell your EZ, you have the responsibility to inform the buyer of any deviations from the plans. Also, be sure the new owner is thoroughly knowledgeable with the owners manual, operational procedures, newsletter, and that he should keep up to date with a subscription to the Canard Pusher. This is the only AD system and all VariEze operators must subscribe.

VARIVIGGEN NEWS
Builder Reports - Jim Saunders of Miami, Fl has flown a really superb VariViggen, N17VV, basically white with red, orange and yellow trim, that has to be the prettiest paint scheme I have seen. Congratulations Jim. Unfortunately after logging only 12 flight hours on his Viggen Jim had a main gear malfunction. His right main collapsed on landing, due to a broken cable, which caused substantial damage. However he has redesigned the main gear system and repaired all the damage and is ready to fly once again. Jim, we are all looking forward to a complete flight test report, and hope to see you at Oshkosh.

Jim Edgar flew his Viggen N101JE on March 13, 1979, he had previously had problems with the cable in the gear retraction system, and in fact had his nose gear collapse on a high speed taxi run. He has repaired it and says it flies hands off. He hopes to make it to Oshkosh.

John Poehner, of Flushing Michigan has his Viggen, N29X, complete and ready to transport to the airport. He only awaits hangar space, and then we should get a first flight report. Lots of luck, John.

Ken Guskott reports that his Viggen N106VV, is very nearly complete. He is in the final stages of engine/cowling installation now. He hopes to fly in early summer, and says he will be at Oshkosh.

Charles Allen has just completed his canopy installation and reports good progress.

Ken Winter and C.M. Schwartz both have their Viggens upside down and the bottom skinned. They had the foresight to apply the dacron to the bottom while the aircraft was inverted. When I built N27MS, I was not that smart, and ended up putting dacron on the bottom, with the aircraft on the gear, and that is quite a trying job! We have one Viggen well along in Australia and at least three in New Zealand. Obtaining parts that far from suppliers can be a problem. Des Whitfield reports that a fiberglass cowling for the Viggen cost $1100 to get to New Zealand!

At least two builders have completed the main gear system as used in N27MS. This is now standard in the Second Edition of the VariViggen plans. For those of you with the first

---

edition who may want a set of the drawings for the main gear system, these are still available from me, here at RAF in Mojave for $10.00 a set.

I now have on record seven VariViggens that have flown and at least two more that are complete and ready to fly. Who knows, maybe we will be able to put up a three ship or four ship formation of Viggens at Oshkosh! Now that would be neat.

VARIVIGGEN SHOPPING

Tony Manis reports that he recently obtained a set of rubber shock donuts for the main gear from Borg Warner in Toronto Canada. These parts are listed as - Borg Warner #31-2014
Anchor #31-2014
Amr. Parts #2-204
and all are exactly the same part. Since quite a few builders have reported difficulty in obtaining these parts, I would appreciate information from anyone who knows of a good source.

Bill Campbell is once again in a position to make pulley brackets and associated metal parts for the Viggen. He also has a large supply of the original 2 1/2" dia LS-806 pulleys available. Anyone interested, please write to Bill at -
P.O. Box 253
Phelan, Ca 92371

VARIVIGGEN BUILDER TIPS

For those of you building the S.P. wing or standard wing in composite, the S.P. wing plans showed the wing root as two plies of BID with flox

corners. We now recommend a better method of laying up the root rib, which is stronger and allow for much easier fitting of wing root to inboard wing, as you can trim the edges for a perfect fit. This can also be used in the S.P. wing aileron tips. See sketch. Layup top and bottom skins normally. Then, after cure, remove .6" of foam from root of wing (or aileron) with a router, dremel, or knife. Sand the exposed inside of the skins, and lay up two plies of BID at 45 degrees to form the root rib. This method is used in the Defiant and make a stronger corner. **SKETCHES OMITTED**

Don Alspaugh of Lithonia Ga, sent in this suggestion for a scarfing jig. The Viggen strength comes from its stressed skin. Good scarf joints of at least a 10:1 ratio are essential.

1) Cut a piece of 1/2" or 3/4" plywood the same size as your table saw top, and clamp it below the surface, to the table with the saw blade below the table, and a guide piece in the miter gauge channel. 2) Turn on the saw, tilt the blade to 5 degrees. Raise the blade to approx. 3 1/2".
3) Select a straight 2" x 4" cut to the length of the table, and lay it parallel to the saw blade just about touching the blade. Accurately mark its position.
4) Remove the plywood top and 2" x 4" and glue and nail it into place.
5) Cut a second piece of plywood, cut elongated holes as shown for carriage bolts, and glue and nail another 2" x 4" to its edge.
6) Place this piece of plywood on top of the first piece. Mark the location of the carriage bolt holes, drill two holes in the first piece of plywood and counterbore them from underneath, so that the carriage bolts are recessed flush.
7) Clamp the two pieces of plywood together using large washers and wing nuts, and replace the fixture on your table saw.
8) Test cut a few scrap pieces and adjust it until the correct sharp edge is obtained (no feathering). Now nail through the plywood into the piece in the miter gauge channel. This piece should be glued. See sketch. **SKETCHES OMITTED**

VARIVIGGEN OWNERS MANUAL CHANGES The best rate of climb speed is not correct in your owners manual, and should be corrected to read 104 mph, not 80 mph as shown. VVOM pg 11. See climb chart below. **GRAPH OMITTED**

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Jim Saunder's Viggen on first flight.

"I am enclosing a picture of the big day---June 14--- when Jess N. Larson, GATO inspector representative from the Minneapolis office, presented me with the airworthiness certificate. The picture shows myself on the left receiving the certificate. In the cockpit is Leo Zeug, my co-builder, who won the coin toss and made the first flight. I followed ten minutes later. The airplane flies beautifully."
Ed Wieland

Everyone is relaxing on the AD-1 wing after loading it to 5.5-g with lead shot bags.

Jiran-prefab VariEze wing at 7.5-g.

AD-1 with wing straight.

AD-1 with wing at 60 degree skew.

N4EZ VariEze, N78RA Defiant, N27MS VariViggen.

Dear RAF,
We have over 280 hours on our airplane, and everywhere we travel people are very pleased and excited with your Eze design because we are generally very satisfied with it especially since we took the toe in out.

We have over 50 hour flying time with other Ezes, Ed and Jo Ann Hamlin, John and Wilma Melville, Les and Olga Faus, and Bruce and Bonnie Tifft. And we have all talked about organizing a VariEze club. So enclosed is a copy of our club's information, and you know, of course, that we would be very much appreciative if you would please print it for us in the newsletter soon. Please let us know if there is any cost.
Thank you, Very sincerely yours,
Donald Shupe.

VARIEZE HOSPITALITY CLUB
Non profit organization to put VariEze pilots in touch with other pilots or builders who would like to share their homes for one or two nights with travelling VariEzers. The idea is to increase communication and friendship between VariEzers and to provide an alternative to expensive motels and car rentals. In addition, we will hopefully have people who could help with parts and repair when needed within a hundred miles or so of every airport. If interested, please send a check of $2. with a clearly printed 3 x 5 card to Dr. Donald Shupe, 2531 College Lane, La Verne Ca 91750, phone (714) 593-1197.

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE. The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $3500 (less engine) in about 1200 man-hours or from prefab parts and materials, costing approximately $5000 in about 800 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect, and repair. The VariEze uses the small four cylinder Continental. The Lycoming 0-235 without starter or alternator can also be used. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 22 gallons of fuel. Frontseat passengers up to 6'4" and 220 lb and backseat passengers up to 6'2" and 220 lb. can be accommodated plus a modest amount of baggage in a suitcase. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM. The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin

and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/ components, manufacturing methods testing, and many other.

THE HOMEBUILDER SUPPORT. The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound 11" x 17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, C85, C90, 0-200
SECTION IIC - Lycoming 0-235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/ color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS AND PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP @ GROSS WEIGHT

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	570 lb
Gross Weight	1050 lb
Range @ Max Cruise	700 mi
Range @ Econ Cruise	850 mi
Landing Speed	70 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6' square feet
Canard Span/Area	12.5'/13' square feet

SPECS AND PERFORMANCE WITH 75-HP CONTINENTAL

Take Off	1200 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	550 lb
Gross Weight	950 lb

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh 72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA SAE, AOPA, AND AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION.
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.

AIRCRAFT SPRUCE & SPECIALTY CO. 201 W. Truslow Box 424, Fullerton, Ca 92632 (714) 870-7551

VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS 4102 Twining, Riverside, Ca 92509
VariViggen welded nose and main landing gear. 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, Co 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8" x 10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air Mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook i including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas,

improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues starting with CP#19 are mandatory for those with VariViggen under construction. Identifies new material sources as they become known. Published quarterly. Price - $4.75 per year first class mail. $6.50 per year air mail overseas. Back issues, $1.00 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the part several years. It covers the entire airplane, including the engine installation fuel system, and not only covers the original standard wing in both aluminum and foam an fiberglass composite, but it also includes the composite S.P. wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65 cu inch size. 555-sq wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines) Price - $475 first class mail, $5.50 air mail overseas.

THE CANARD PUSHER NO 21 JULY 79

RUTAN AIRCRAFT FACTORY
Bldg 13, Mojave Airport,
Mojave, Ca 93501
(805) 824-2645

U.S. & Canadian subscriptions - $4.75
Overseas (AIRMAIL) - $6.50
Back Issues - $1.00 each

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 21. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 21. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 21. If you are building a VariEze from the 2nd Edition plans you must have newsletter 16 through 21. A current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 9:00 to 12:00 and 2:00 to 5:00 on Wednesday through Saturday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins. Our building will be closed 26 July to 9 August during Oshkosh convention.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions" This will speed your reply.

CONGRATULATIONS! There have been a very large number of first-flights of VariEze's since April, averaging about one every three days. The following list is of VariEzes' first flights that RAF has been notified of since our April newsletter.

Eric Larson	San Diego,	Ca
Lou Mason	San Antonio,	Tx
Tom Franken	Great Fall	Mont.
Jim Davis	Falls Church	Va
John Neils	Bozeman	Mont
Bob Ohletz	Thousand Oaks	Ca
Norm Ross	Victoria	Canada
Bob Purdy	Carbondale	Ill
Ray & David Ganzer	El Cajon	Ca
John Wagner	Pontiac	Mi

Canard Pushers from 1 to 82

H.A. Bowman	Anchorage	Als
Ike Griswald	Phoenix	Az
George Gilman/		
Otto Schimmel	Santa Paula	Ca
Harold Heiman	Aurora	Ill
Carlos Amspoker	Martinis	Ca
Robert Vaughan	Nashville	Tn
Mel Blanchard	Independence	Or
Bob Mudd	Albuquerque	N.M.
Chet Ellingston	Huntington Bc	Ca
Bruce McKinney	Belmont	Ca
Dick Davey	Boise	Id
Riley/Walkton/Beenson	Swickley	Pa
Ben Duarte	Dallas	Tx
Loyd & June Foster	Mt Shasta	Ca
Don Youngs	Palo Alto	Ca
S. Cochran	Swanton	Oh
Jack Day	Reading	Ca
Dan Laurence	Hopwell	Va
Bob Wahrmund	Austin	Tx
Mick Hinton	Kororo via Coffs Australia	

This totals of 126 VariEzes that we have heard of that have flown. Now, if we all arrive at Oshkosh Saturday in formation - - - - - -!!

RAF ACTIVITY Since the April newsletter has included builder support, development and test of the Long-EZ, and refining our Defiant - VariViggen - VariEze airshow routine. Also, we have run a complete series of workability tests with SAFE-T-POXY, the new epoxy that now allows sensitized people to hand laminate.

OSHKOSH 79 should be a big year for the canards. We expect that 25 to 50 VariEzes, VariViggens and Quickies will fly in to the EAA convention July 28 to August 5. We will attempt to reserve two rows immediately north of the access road so we can all park together. We plan to organize a daily pilot's bull-session at the airplanes. Here's the RAF forum schedule:

VariEze	1 Aug	3pm
VariViggen	3 Aug	3pm
Defiant	2 Aug	1:30 pm
Quickie Design	31 Jul	3 pm
College	2 Aug	10:30 am

Tentative schedule for RAF Airshow - (Defiant/VariViggen EZ formation)

Sunday	29 July
Tuesday	31 July
Thursday	2 August
Saturday	4 August

GOOD NEWS! BREAKTHROUGH IN EPOXY
The new low toxicity epoxy from Applied Plastics, is now approved for release to our raw material suppliers, Wicks and Aircraft Spruce. The epoxy is called SAFE-T-POXY, which is a registered trade name. RAF has

done a considerable amount of testing of this material, and have found it to be as good or better in all respects as the RAEF and RAES and you will no longer have to worry about which to use. Safe-T-Poxy does not exotherm, and can therefore be used in both large and small lay ups with low danger of heat/foam damage.

Response from those builders testing Safe-T-Poxy has been 100% positive, even though the samples were not as easy to work with from a "thickness" standpoint.

We are very pleased with this development, and proud to have been associated with Applied Plastics, in this milestone in epoxy development. Results of one of the test follows:

Attention: Mr. Burt Rutan Subject:
SP-10 Epoxy Tests.

The Applied Plastics Co. sent samples of the new, low toxicity, epoxy system for home tests. The results of my test are listed on the attached page. In summary, there were no detectable toxic effects whatsoever.

Thank you for developing this new epoxy system, it is another significant contribution to the aircraft industry.

Sincerely
Paul J. Bryant
Prof. of Physics and
Lecturer in Medicine.

SENSITIVITY DATA RECORDED FOR TWO EPOXY SYSTEMS RAE & SP-10

Parts of body effected	Symptoms. RAE	SP-10	Duration of effect RAE	SP-10
Back of hands & wrists	dermatitis rash	no effect	48 hrs	none
palate and throat	soreness & reddening	no effect	7 days	none
sinuses and forehead	moderate headache	no effect	8 hrs	none
finger tips	hardened flaking	no effect	10 days	none
forearms	itching	no effect	4 hrs	none

Since the ratio of resin to hardener is different than the previous APCO epoxy, see CP20 for the necessary changes to your balance scale. If you have "Michael's Engineering" ratio pump it will need to be reconfigured before you can use it to ratio Safe-T-Poxy. See the sketch on page 9 for a simple way to do this. We have done this and have good results.

VARIEZE OPERATOR EXPERIENCE. We've been criticized by some VariEze flyers that our newsletter covers only builder support and modifications and when covering flyers we discuss only accidents or problems, but not the fun part. With this in mind, the following section summarizes' some of the information we have received concerning VariEze "social life".

First, activity from the VariEze Hospitality Club (CP #20, Page 11)

"This is the 1st Annual International VariEze Hospitality Club flyin at Mariposa. The largest assembly of VariEzes since Oshkosh 78. There were ten Ezes flew in plus two builders of nearly complete birds.

Les and Olga Faus	N14533
Ken Forrest	N84ST
Gerald Gardnor	N99EZ
Julie and Bill Lermer	N51820
Ed & Joann Hamlin	N777EJ
Ron Kaporman	N16EL
Dan & Mark Lee	N35EZ
John & Wilam Melville	N76WJ
Donald & Bernadette Shupe	N39EZ
Bruce & Bonnie Tifft	N115EZ

Everyone except three stayed with Bruce's parents, brother, and relatives for one night and had great times telling lies !!!

"Pine Mountain Lake VariEze Hospitality Club fly in over Memorial weekend. Faus, Hamlins, Melvilles, and Shupes rented a house for the weekend, and it was great! The Ezes were parked just off the Pine Mountain runway on the land of Charlie Lynn, builder of the Mini-Mustang. Pine Mountain, with runway access lots and friendly people captured the hearts of the attendees."

"We have planned another informal VariEze flyin to be held October 20-21 at Columbia, Ca. Notices with details are being mailed to all the Eze owners that we have addresses for. We need to give the airport people at Columbia some idea of how many airplanes we expect, so please get in touch with the below listed people for further details if you would like to attend. Hope to see you all at Columbia in October."

Bruce and Bonnie Tifft (805) 649-2721
Bill and Julie Lermer (714) 462-0904
Hotels: Columbia Inn (209) 532-7357
Stagecoach (209) 532-4508
City Hotel (209) 532-1479
Campground at edge of airport also.

Ray and Nova Cullen recently visited RAF in Mojave in their newly completed and very beautiful VariEze. They did a super job on their EZ and are both concerned about builders who are having difficulty with their projects. They have expressed a sincere desire to assist other EZ builders in their area. Call (503) 842-5440 or write

Ray and Nova Cullen
1116 6th Street,

Tillamook Oregon 97141
Thanks Ray and Nova, this local help is extremely important to builders needing assistance.

FLASH! Peter Kraus flew his VariEze at the Paris Airshow, in an impressively smooth, low level, aerobatic display!

We understand that Johnny Murphy, builder of VariEze N20VE has, together with his brother, built and flown a Quickie. That makes two E-Z builders who have completed and flown a Quickie. We hear that he was just elected Mayor of his hometown, Cape Canaveral, Florida. Congratulations, Johnny !!

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Mariposa.

Pine Mt. Lake.

Ray & Nova Cullen.

Lee & Dianne's Trio.

Norm Ross' EZ - 1st in Canada.

A. Hinton's EZ.

Lee and Dianne Herron own a unique set of three airplanes - see photo. They were the first homebuilders to fly off restrictions on a VariEze in 1977. They were the first homebuilders to fly a Quickie. Their VariEze cruises at 190 mph on 100 hp. Their Quickie and Cessna both cruise at 125 mph on 19 and 100 hp respectively! Their Quickie's takeoff distance and cruise speeds are better than the Quickie manual performance figures. Lee and Dianne built their Quickie in 111 days and 525 manhours.

Note: Address any Quickie correspondence to Quickie, not RAF. Quickie, Bld 68 Mojave Airport, Mojave Ca 93501 (805) 824-4313

A. Hinton
RMB 13 Woolgoola Rd
Kororo Via Coffs Harbour
N.S.W. Australia

Dear Burt,

I would like to inform you that my VariEze VH-EZH is now flying (fantastic to say the least). It weighed out just under 600 lbs with alternator and limited I.F.R. panel.

Thank you very much for your help, which has allowed me to build this magnificent machine. It flies hands off and I just can't stall it, but will be going back into the work shop soon to install the wing cuffs.

After the necessary flight tests in March of this year, I was able then, accompanied by my wife to do my longest flight in EZH and enter my EZ in the SAAA convention of the year at Bowral N.S.W. I am very proud to say it won the Reserve Grand Champion home built of Australia. This was my first attempt at building so mere words will never express how I felt that day.

Since the air show my phone has rang constantly with inquiries from future builders of the VariEze.

Hope to see you at Oshkosh this year.

Yours faithfully,
Mick Hinton.

The Photo on pg 2 shows Norm Ross' beautiful new VariEze. It weighs 603 lb, yet has full electrical system, I.F.R. panel and leather upholstery - it is the first Canadian EZ to fly.

Some comments from Dr. Jim Wright, Kansas City. "I have noticed an early tendency on the part of everyone flying 26JW to have the right wing drop momentarily on lift-off, even with the two TWA pilots, and talking with them I believe its related to our tendency to want to keep the stick vertical rather than canted to the left. We all have a lot of stick time and maybe just keep it "in the middle" by habit. When we have thought about that and remembered not to "force" the stick to be vertical the wing does not drop. I've made a couple of cross country flights, and on one short one, KC to Jefferson City, Mo., I got a ground speed of exactly 200 mph, checked out by time and crossing the departure field at altitude and checking time as I crossed the Jefferson City airport at same altitude. I took one trip KC to Houston Tx., Port Arthur, back to Houston, Fort Worth, and back to KC. Put 14 hours on 26 JW and used 64 gallons. That's 4.57 gals/hr! I cruised at from 8,000 to 11,500 at about 65 to 70% power, but also did a lot of take offs and landing joy riding friends. I used one quart of oil on the trip! I'm pleased with and proud of 26JW, and thank you for a good design and fine support program. When a VariEze pilot goes into a new airport he is, indeed, a celebrity and all the hard work to get a well built aircraft is worth it. And I suggest to all who are about to buy a prop and want a really good performer at reasonable price that they talk to Ray Hegy."

More from Nat Puffer, Minneapolis, who owns one of the cleanest EZ's around. His 85hp Ez is faster than most of the 100 hp ones. "Don Rosborough, VariEze builder from Philadelphia, stopped in and I took him flying. After letting him fly from the back seat, and doing wing overs, the air was smooth so we opened it up at 4000ft. We hit 175 mph indicated which we calculated was 188 TAS at a density altitude of 5000. That looks like about three mph better than your curve for a C-85, and translates to 195 mph sea level. There are still a few things I can do yet to squeeze a few more mph out:
1) Aileron gap seals
2) Seal the large trim gap on my rudder, which I don't use.
3) Herb Sanders trailing edge exhaust pipes. I would like to say some day that I have a 85 hp, 200mph airplane!"

PHOTOS OF EZ N4EZ AND LONG-EZ N79RA OMITTED

N79RA - LONG-EZ. The Long-EZ equipped with Fred Jiran's prefab wings made its first flight on June 13th, 1979, and is in the middle of a rigorous flight test program at this time. We have put 30 plus flight hours on it to date.

The design goal for the Long-EZ is a comfortable, two place, cross country airplane, with long range and the capability of carrying a starter and alternator on the 0-200 or 0-235 without the penalty of lead ballast in the nose. Of course, having a larger whetted area and being heavier it is not as fast nor as spritely as a standard VariEze. This aircraft was designed for those people who insist on having starter, alternator and full electrical. The Long-EZ has longer range, more wing area and wider fuselage than a VariEze. It sports a nose rudder using conventional rudder pedals and toe brakes.

This is all the information we have to release at this time and we would appreciate it if you builders interested in Long-EZ please wait until our test program is complete. As you know, our policy here at RAF, is that until we are ready to sell anything, we will not encourage anyone's interest, until we have a marketable product.

If the Long-EZ completes a successful test program we will market a Section VII. (Long-EZ addendum). You will be able to use your VariEze plans. The canard, elevators, wings and cowling are the same as a VariEze. Do not assume that the Long-EZ will be available. It's acceptability depends on the success of the remainder of a very thorough test program. If successful, the Long-EZ addendum will be available this winter. Look for an update this October in CP#22.

ROTORWAY RW-100/VARIEZE UPDATE We still have not begun any formal RW-100/VariEze compatibility testing. We have received no information from Rotorway that the developmental deficiencies we consider necessary to begin testing (stated in CP #20) have been corrected. Again, we must caution our builders that until the deficiencies have been corrected and an acceptable testing of reliability and performance has been established, we will be unable to ascertain the acceptability of the RW-100 or any other alternate engine for the VariEze.

IMPROVEMENTS/CHANGES - MANDATORY?
Modifications, improvements, and changes in our newsletters have not been specifically tagged as to their mandatory nature. These recommendations have, instead, been verbalized in the description accompanying the change.

We at RAF, of course, can not enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety. We are therefore listing past and future changes in several categories.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.

Note that changes correcting plans errors are not listed. Only those that could be interpreted as flight safety items are listed. Read all your newsletters, this is not a complete list.

Be sure you check the following list against the current status of your aircraft.

VARIVIGGEN

Category	CP#	Change & Page
DES	1-2 + 21-8	Trim tabs on Viggen elevators
DES	2-2	Reflex Thd double advance
MAN-10HR	2-2	Remove upper O-ring

VARIEZE		
Category	CP#	Change & Page
MAN-GRD	10-6	Fuel tank drains
MAN-GRD	11-5	3-tank fuel system
MAN-GRD	11-7	UND wrap on C/S spar
OBS	11-A1	Spoilers - obsoleted in CP12
MAN-GRD	12-9	1.7" dim on tab
MAN-GRD	12-18	Replace elevons with ailerons, remove spoilers (see CP13-2)
MAN-GRD	14-6	All-glass maingear tabs
MAN-GRD	14-6	Shorten Canard - New cg ranges (if cg requires)
MAN-GRD	14-8	Drill hole in inlet hose
MAN-GRD	15-2	25-hour interval on fuel filter inspection.
MAN-GRD	15-2	First flights only - strip all unnecessary weight out before first flight
MAN-GRD	16-4	Contour canard within 0.006
MAN-25HR	16-5	NG25 or new-design NG15A (CP 18 pg 4)
MAN-25HR	16-6	Inserts in brake Nylaflow low fittings
MAN-GRD	16-9	Safety cables on short stacks see also CP18
MAN-GRD	17-5	Wide-chord elevator. DES or OPT if you are already proficient in flying your narrow-chord EZ. MAN for new aircraft
MAN-GRD	17-6	Canopy safety catch
MAN-GRD	17-4	Replace valve if stiff
MAN-25HR	18-5	Gascolator and fire resistant fuel lines.
MAN-25HR	19-3	Worm-drive nosegear. MAN-GRD for new construction

MAN-25HR	19-2	Wing cuffs. Also, limit cg as shown until cuffs are installed
MAN-GRD	19-4	Rebuild elevators if more than .3 lb required to meet balance angle. 1/2 Additional weight must go at tip balance area.
MAN	20-3	UND Beef on main gear. MAN for new construction, and on operational aircraft if gear creep is experienced.
MAN-GRD	20-4	1/4" rod ends in pitch system.

Sally, shutting down after her first solo flight in Viggen N27MS. Mike, ready for a kiss! **PHOTO OMITTED**

VARIEZE PLANS CHANGES

Section IV pg 30	delete "light grease on nosegear guides" and change to "light grease on worm and wormgear".
Section IV pg 37	add "before first flight, clean and flush all screens, both carb and gascolator. Remove and clean out carb float bowl and finger strainer.
Clarification to C.P. #19 pg 7.	When retrofitting the crankdown nose gear system, Discard: Reuse: NG 13 NG 9 NG 11 NG 10 (cut down) NG 12 NG 14
Section IIC pg 36	Fuel system shown is obsolete Follow page 7,10,11, & 17
Section IIC pg 27	Material for throttle and mixture controls is .062 2024T3 aluminum Also, see Pg 9.
Section I	Construction Order. Build fuselage first and canard and elevators last.

The reason for this change is simply that the canard and elevators is the most important and critical part as far as accuracy is concerned, on the whole airplane. Rather than learning to use the materials while building such important parts, we want you to learn to handle the foam and fiberglass-epoxy while building such simple parts, as fuselage bulkheads, seat backs and fuselage sides. Then work your way into assembling the fuselage and making the bottom. Follow the plans from here, and finally last of all, build the canard and then the elevators. By this time you will be thoroughly proficient and should be able to make excellent parts.

ELEVATOR BALANCE (continued) Here we go again!
It may seem that we harp on about the elevator shape and balance, but the fact remains that the single most important parts of the airplane are the elevators. Recently, since CP20, we have had yet another builder who experienced elevator flutter. It occurred at 120-130 mph and produced such a violent shaking, that he was certain the airplane was going to come apart. It turned out that he had extended his elevator's trailing edge and found he had to add weight. Unfortunately he added considerable weight only to the inboard, and none to the outboard counter weight. This is a NO NO!! It is critical that any extra weight added to balance the elevators to 10 degrees - 20 degrees nose down (up to a maximum of .3 lb) be equally divided between the inboard and outboard. Keep your elevators light! In his case, these elevators weighed around 5 lb a piece, which is totally unacceptable. If yours are over 3.9 (lt) or 3.6 (rt) balanced, strip them to bare tubes and start over.

While we are on the subject of balance I want to clarify the method of measuring the 10 degrees - 20 degrees nose down angle. A few builders have been using the flat bottom of the elevator, which is wrong.
SKETCH OMITTED

INITIAL FLIGHT TEST
As new VariEzes emerge from their concealed assorted construction sites and start taking to the air for the first time, the great majority of the pilots report no problems, "the aircraft flew great, just like the book". However, a few are still having control problems during initial flights. When we investigate the problems we often find a pilot who is neither current, proficient, familiar enough with the VariEze owners manual, or does not understand that a VariEze does not fly like a Cessna 150 or some other sluggish trainer. The VariEze is high performance, responsive aircraft with differences. It has a side stick and the pilot should keep his forearm on the arm rest and use his wrist to control pitch. Also, the rudders can both be inadvertently deployed at the same time and the pilot should be careful not to do this in flight. Jim Davis got a little tense and unknowingly pushed both rudders simultaneously giving him yaw-roll problems. (see his story below). Another pilot reported very poor climb and he said he almost hit a small hill on his first take off. I was concerned until I found out he was holding 130 mph, thats 38 mph above best climb speed, no wonder the climb rate was low. The nose and canard attitude gave him the impression he was climbing when he wasn't. I flew first flights on two new VariEzes here at Mojave. Both aircraft flew normally, but both pilots had problems when they first flew on their own. One pilot rounded out high, got real slow on landing and hit the winglets on "crunch-down". The other pilot had pitch control problems (PIO) and damaged the nose gear. He was trying to fly with his whole arm instead of just the wrist.

Lets discuss the three common areas that seem to give a few people problems.

1. The non-standard rudder pedals. Beware not to push both at the same time in flight. One will usually be out more than the other producing unwanted yaw. The VariEze rudders are very effective and the yaw generated couples easily to roll. In fact the roll rate will

almost double with rudder added to aileron control. Adjust the pedals so your foot does not press the pedals naturally.

2. Pitch over-controlling. The novice pilot will expect the VariEze to handle like the C-150, or what ever, he last flew. The experienced pilot knows that J-3 cubs and Bonanzas handle different and will make the transition easily. Spend enough time on the runway just above rotation speed but below lift-off speed and practice controlling pitch so you can put and hold the desired/selected pitch proficiently. Hold the forearm on the arm rest and control pitch with wrist only. Do not over-rotate! The highest rotation you should see during this or the later flights is the canard up to, but never above the horizon. Better yet, keep it always at least 2 degrees below the horizon.

3. Nose high, Slow touch down speeds. To avoid this be sure that during take off and landing to not rotate the nose above the horizon. On take off rotate the nose/canard to just below the horizon. Hold it there and wait for lift off. On landing, fly final and touch down while you can still easily see over the nose. If you cannot see the runway, go around and use more speed next time. You will find that using this technique you will be a little above the minimum touch down speeds. This is okay to be a little fast for your first few landings. Runway length notwithstanding a hot landing in a VariEze is no problem and is much better than a slow, wing rocking, blind "arrival".

The following is from Jim Davis' about his first flight experience: "On first flight, I experienced unusual roll on climb out and level flight. This occurred unexpectedly, both right and left at a random rate. First landing was exceedingly hard and resulted in damage to the main gear, wings, etc. I believe this was due entirely to pressing on the rudder bars inadvertently. I had flown back seat of another VariEze and experienced the unusual sensitivity of the controls. However, this didn't carry over well to the rudders which I had been tromping on for brakes during two hours of high speed taxiing. Rudder cable length was short, cut to insure solid brakes with toes down. Seat cushions, adjusted to other Rutan criteria definitely accentuated the problem. I didn't

---

realize the unusual roll induced in swept wings by rudder action.

Suggestion: Make sure your rudder cables are long enough to keep foot pressure off rudder bars without any effort. Make every effort to ride the backseat of another VariEze before first flight in yours. Fly dual in a Thorpe T-18 or other small plane with very sensitive controls and speed on final of 80 mph. There is really no substitute for this experience - and keep your feet off your rudder bars unless you want yaw and plenty of roll."
Jim Davis, Falls Church, Va

Another area we need to emphasize is weight. During the initial flight testing "KEEP IT LIGHT". Our philosophy is "if it isn't needed for first flight don't put it in". Give your aircraft every chance of successfully completing the test phase. If you keep the weight out of the tail (gen/alt/starter/pump etc) you don't have to ballast the nose

as much to get the cg into the "first flight box". Remember the aft cg limit might not be the same for your aircraft as it is on N4EZ due to builder differences. Be careful, work toward the aft cg limit gradually.

Another question is "why wear a parachute during flight test"? Will I hit the prop or the canopy or should I slow up and roll inverted - - - ? Remember your aircraft may not fly like N4EZ or a builder error could cause destructive flutter or a loose fuel line could cause a fire, or many other things. In any of these cases the parachute is the only means of survival. As for how to bail out - - - you open the canopy unfasten the belt and jump over the side. Don't worry about the prop, you will fall away from the aircraft long before you get blown back into the prop. You need 250+kt before prop contact should be a factor. Remember if you find yourself in a situation where staying with a stricken aircraft means death and the parachute is a chance to live, I think I would take that chance no matter what the odds were. It sure is comforting to have a chute on your back to get home with in the remote chance the aircraft came apart. As a two time member of the Caterpillar Club, I recommend parachutes enthusiastically. (Above comments by Dick Rutan)

ACCIDENT Fuel contamination: Steve Stuff had an engine failure just after take off and damaged his VariEze running off the end of the runway. The failure was due to debris in the carb float bowl blocking the main fuel jet. Therefore, we are changing Section IV to clean the screens and the float bowl after the engine/taxi runs but just prior to first flight. Note that Section IV already requires a 25 hour inspection and cleaning of the gascolator.

Did you know: that a Boeing 727 can run over you (midair) and not ever see you? Reference Aviation Week report on the San Diego midair-they found that when the airline crew is in their usual sitting position (slightly down or back from the recommended position) it is possible to run into you and never see you, even if they are looking, because the windshield wipers will obscure you from their view. "You all be careful now."

BUILDERS HINTS Bob Lokey, of Universal City, Texas, recommends the following method of repairing a bad gouge in blue foam. Use a 1 7/8" dia hole saw with the guide drill bit removed, and turn it by hand centered over the damage until about 1/2" deep. Remove the center `plug' with a chisel. Now use a 2" dia hole saw with guide drill bit removed, and cut a plug from some scrap foam. Paint a little slurry on the bottom of the 2" plug, and "screw" it into the hole made by the 1 7/8" dia hole saw, until it firmly bottoms out. Use a hard sanding block to sand it down flush. Bob says it works beautifully. Don't neglect to use slurry to glue the plug in, though, a plug, just forced in dry is not structurally acceptable. If you need to hot wire through the plugged area, leave out the slurry until after hot wiring is complete, then slurry and nail the piece in place until cured.

Several builders have purchased the CD1145 worm gear from Boston, and have received a webbed cast gear with lightning holes in the web. This gear can be used if you follow this procedure: Remove all grease, and sand blast or sand with 60 grit, the webbed area. Lay the gear down on some Saran wrap on a flat surface. Now mix up some flox and trowel it

into the lightening holes making sure to get good squeeze out, and thoroughly fill all voids. Trowel off excess, level with the gear and allow to harden. Now drill and countersink 4 #12 holes for AN509 bolts and bolt to NG steel weldment. This system works great, we have it on N4EZ with no problems. Viggen builders can use the same method in the worm-wormgear main gear system as it uses the same Boston gear.
SKETCH OMITTED

FEATHERFILL some builders have not read their newsletters and are still experiencing problems with feather fill. This newsletter bulletin supersedes all previous instructions including Section V on Finishing. Before attempting to apply featherfill - surface must be dry, dull and clean! A "fog" or "tack" coat (very light coat) of featherfill should be sprayed or brushed on and allowed to "tack" up for 10 - 20 minutes. Now mix up a batch of featherfill (must be thoroughly mixed using a paddle or wire in a drill press) and mix 25% - 50% micro balloons by volume into the featherfill. Use a 2" brush, and brush it all over the part you are working on. Allow this to cure thoroughly, then dry sand using new 100 grit and a spline. As soon as you see glass high spots quit! Again brush on featherfill - micro balloons in any remaining low places, allow to cure and sand with 100 grit and spline. Generally these two applications as described above will be sufficient for all but the worst surface, three applications at the most. You should use 1 1/2 gallons at the most on a VariEze.

Some people have had problems with their Rosenhan brake discs. Mr. Rosenhan is selling an excellent replacement disc direct from him for $10 each.

Note that the styrofoam referred to in the plans as blue foam is not as blue as it once was, in fact some builders have reported receiving almost white foam. This is ok, just be sure it is styrofoam, which it will be if you purchase it from one of our designated suppliers Wicks or Aircraft Spruce.

The speckled paint finish as seen inside Fred Keller's cockpit at Oshkosh last year, is "Zoletone" which is available from most paint supplies, one of which is Paramount Paints, Westminster, Ca.

Joe Deady reports that he has been using a pair of ski goggles when sanding or grinding with excellent results. The soft foam seal is designed to keep out fine particles like snow and conforms to your face, even with a dust mask on, and it stays completely fog free.

Installing Jiran Fuel Tanks. The fuel tank bottoms are pretty straight forward, but don't forget to remove the peel ply!! Then paint a generous coat of pure epoxy all over the inner surface of the tank. Do this with the tanks at the same temperature as the shop. (Don't bring them into a cool construction environment, after they have been stored in a hot shed, or vice-versa).

When you get ready to put the Jiran fuel tank tops in place, do not build a small "ledge" along the fuselage as shown for the home built tanks. Cut a 3" wide strip of BID at 45 degrees and lay it up on the edge of the tank top, lapping onto the tank 1 1/2". Be careful not to wet the 1 1/2" overhanging half of the BID tape. Allow this to cure for three hours, then install the tank top with flox and tapes, and wet

out the BID tape onto the fuselage as shown. After this cures, trowel dry micro into any gap between the tank and fuselage and apply two BID tapes over this joint lapping equally onto the tank and fuselage. **SKETCH OMITTED**

When making your main landing gear attachment tabs, in Section I chapter 18, you are told to lay up your pads on a `piece of paper', do NOT use waxed paper in this application, as it is possible for the epoxy to pick up wax, and then to have in effect a wax barrier between the tabs and the gear leg.

Caution Do not ever hand prop a VariEze (or any airplane) that does not have at least one functioning impulse mag. An impulse mag allows the plugs to fire at or slightly after top dead center, without an impulse mag it will fire up to 25 degrees before top dead center, which can lead to broken thumbs at the very least. If you only have one impulse mag, be sure you select only that one until the engine is running.

Safety Hint. This suggestion comes from Lee Herron. "It has been pointed out by the F.A.A. Eastern Region E.M.D.O. that the canopies of the bubble-type found on VariEze, Quickie, KR-2 etc., are impossible to break or open with the bear hands in an emergency and not all emergency personnel know to freeze the Lucite canopy with Carbon Dioxide before it will break. Therefore, an emergency canopy opening system is desirable.

An acceptable answer was found when using MS20001 type hinge, the hinge pin is replaced with 1/8" stainless music wire that has a one inch finger loop at the front end. A 1/8" hole is then drilled into the base side of the hinge and the wire loop end snaps into this hold and locks the pin in place until pulled to release the canopy in an emergency. To finish the job, use 3/8" red "stick-on" letters along the hinge "PULL EMERGENCY". Simple and safe. **SKETCH OMITTED**

Noel Bramich, first VariEze to fly in Australia, had tremendous overheating problems on a Rolls Royce O-200. He finally traced it to too small of a main jet. EZ builders - take note!!

Junking of non perfect parts. We have received many calls lately from builders who have a poorly built part, too heavy, dry lay up, etc. Also builders who are determined to use epoxy that has expired (Lambert). Try to put yourself in the position of a manufacturer of a certified airplane. If any parts don't meet quality control specs, or if any material is over shelf life, it is thrown out and not used. You are building an aircraft that you will trust your life to, do not use substandard parts, or expired shelf life materials. In the case of expired epoxy, use it to build a boat, remember you can swim a whole lot better than you can fly.

VARIEZE SHOPPING. Props for the VariEze are available from the following vendors. We have evaluated sample props from these suppliers and have found workmanship and performance to be excellent.

Stan Cooper reports excellent results to an ad in Trade-a-plane for an engine for his VariEze. He bought a Cont. C85 for $1300 with 430 hours on it and heartily recommends going this route.

NOTE!! H.C. Communications reports that they will Not be able to fill antenna orders placed after September 1.

VARIVIGGEN NEWS
I have heard from quite a few Viggen builders since Cp20, and it seems that we will have several new Viggens flying during the summer. We only have one report of a first flight this time and that is John Poehner of Flushing Michigan. He reports excellent flying qualities and is very happy with everything but his main gear system. Congratulations John.

N27MS has flown regularly and on June 19, Sally solo'd our Viggen for the first time. She has flown it regularly from the front seat but I have never had the guts to get out and let her go solo! I finally could not put it off any longer and she went out and made three perfect landings. Sally's total flying time is 120 hours, mostly in C-150's and with a little Grumman Tiger time. The only problem is now our Viggen will not always be available for me to fly!! Congratulations Sally.

N27MS now has 298 hours total time, and for the first time we have had a minor failure. During a routine preflight I noticed a small crack in the skin under the wing attach fittings on the aft side and parallel to spar E. (see sketch) This crack was caused by torsional loads on the outboard wings, when large abrupt aileron deflection was used, i.e. abrupt rolling maneuvers.

There are two ways to prevent this: 1) on a new aircraft, before applying dacron, use three plys of UND (unidirectional) glass, layed up parallel to the butt-line over the skin crossing the ends of spar E. This should be done top and bottom on both left and right wings. On an already completed aircraft, the finish including the dacron must be removed down to bare wood. 2) The same repair may be made using a strip of 3/32" birch plywood tapered all around. Grain must be parallel to the buttline. **SKETCH OMITTED**

I carried out this repair on N27MS using 3 ply's of UND glass. The first ply was 2" wide 10" long, the second ply was 2" wide 8" long, and the third ply was 2" wide 6" long. The airplane has 15 hours on it since the repair in really turbulent air with no further sign of a problem.

An omission was made in the second edition of the VariViggen plans. The high speed fixed trim tabs, which are discussed in the technical report are not shown. They should be installed on each elevator to improve trim characteristics (speed stability). Each tab consists of a balsa wood airfoil epoxied to two booms (1/4" hardwood dowels, or fiberglass arrow shaft stock) which are epoxied into 1/4" slots notched into the trailing edge of each elevator. The booms increase the tabs effectiveness at high speed and prevent the the tabs from reducing maximum elevator lift. This allows the bungee trim system to function normally. **SKETCHES OMITTED**

VIGGEN SHOPPING
I've had several reports that the rubber shocks for the main gear are readily available through Genuine Auto Parts or NAPA. Doan #31-2014 NAPA #602-1015 made by Balkap.

Aircraft Spruce and Specialty report that they can now offer all raw materials and purchase parts required for the VariViggen main gear retract system used on N27MS.

Those of you using the worm-wormgear main gear retract system, see page 6 of this newsletter for the correct method of using the CD1145 Boston worm gear.

When building outboard wing tanks in S.P. or composite standard wings, use 9mm thick 6 lb/cu. ft. pvc (red) foam instead of urethane. Scrounge some from your buddy who is building a VariEze, or buy it from Wicks or Aircraft Spruce and Specialty.

"BIRTH CERTIFICATE" FOR FOSTER'S VARIEZE N77LF OMITTED

CARTOON OMITTED

EPOXY PUMP MOD Modification to Michael's Engineering epoxy ratio pump, to dispense 100 parts resin to 44 parts hardener for use with the new Safe-T-Poxy. See sketch and note that the linkage pivot on the

hardener piston is moved 1/2" closer to the linkage pivot on the resin piston. The original pivot is removed and extended to a position 35 inches away by bolting a length of 1" conduit to the existing handle. It is important that the entire pump assembly and the new pivot point be securely clamped or fastened to a common board or table such that there is no movement between the two. This gives nearly equal travel of both pump cylinders. Now mount a small wood block under the handle so that you limit the amount of 'stroke' on the pistons, such that they do not bind or tend to come out of their respective cylinders. **SKETCH OMITTED**

LYCOMING THROTTLE/MIXTURE SUPPORT The Long-EZ was our first experience at installing an 0-235 Lycoming, since the Section IIC was developed by AirSport. We found the throttle/mixture support in Section IIC (pg 27) to be too flexible and almost impossible to build. We redesigned it, as shown. It now is a "gasket" between the carb and engine and requires two normal gaskets (either side) when installing the carb. The small tab on the aft end should be bolted to a .063 x .6 aluminum strap. The strap is bolted to an oil pan bolt. Apply additional damping by bonding the support to the oil pan with silicone rubber sealant. The large hole in the support provides clearance for the oil drain. When rigging the throttle and mixture controls be sure the cable clamps are positioned to aim the cable directly at the actuated arm, with as little flexing as possible. The controls must work without the return springs. Check this before installing the springs. The springs provide better snub and eliminate slack. The throttle and mixture springs return to full open and full rich, should a cable fail. The throttle return spring can be attached to the firewall. **SKETCHES OMITTED**

WING AND CANARD AIRLOADS Canard Pusher No. 10 presented spanwise airloads data for the VariEze. These data are obsolete due to two changes: 1) shortened canard (142 inch) and 2) farther aft cg limit increases wing load. The data listed below is for the wing and canard at limit load factor of 5-g. Also the simultaneous 4000 in-lb winglet bending moment is applied at the wing tip. All data are for 1050 lb gross weight and worst-case cg positions. When doing any static load testing be sure to position the weights centered about the 1/4 chord position (chordwise distribution).

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE. The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $3500 (less engine) in about 1200 man-hours or from prefab parts and materials, costing approximately $5000 in about 800 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect, and repair. The VariEze uses the small four cylinder Continental. The Lycoming 0-235 without starter or alternator can also be used. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 22 gallons of fuel. Frontseat passengers up to 6'4" and 220 lb and backseat passengers up to 6'2" and 220 lb. can be accommodated plus a modest

amount of baggage in a suitcase. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM. The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/ components, manufacturing methods testing, and many other.

THE HOMEBUILDER SUPPORT. The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound 11" x 17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, C85, C90, 0-200
SECTION IIC - Lycoming 0-235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/ color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

SPECS AND PERFORMANCE WITH 100-HP CONTINENTAL, FIXED-PITCH PROP @ GROSS WEIGHT

Take Off	900 ft
Climb	1600 fpm
Max Cruise	195 mph
Econ Cruise	165 mph
Empty Weight	570 lb
Gross Weight	1050 lb
Range @ Max Cruise	700 mi
Range @ Econ Cruise	850 mi
Landing Speed	70 mph
Landing Distance	900 ft
Wing Span/Area	22.2'/53.6' square feet
Canard Span/Area	12.5'/13' square feet

SPECS AND PERFORMANCE WITH 75-HP CONTINENTAL

Take Off	1200 ft
Climb	900 fpm
Max Cruise	172 mph
Econ Cruise	145 mph
Empty Weight	550 lb
Gross Weight	950 lb

THE FOLLOWING ARE RAF-AUTHORIZED DISTRIBUTORS OF VARIEZE MATERIALS AND COMPONENTS. CONTACT THE DISTRIBUTORS AT THE ADDRESSES SHOWN FOR THEIR CATALOGS AND DESCRIPTION OF ITEMS

ALL RAW MATERIALS

AIRCRAFT SPRUCE & SPECIALTY CO
201 W. Truslow Ave. Bx 424,
Fullerton, Ca 92632
(714) 870-7551
Catalog $3

WICKS AIRCRAFT SUPPLY
410 Pine,
Highland, Il 62249
(618) 654-7447
Catalog $2

KEN BROCK MANUFACTURING, 11852 Western Ave. Stanton, Ca 90680 (714) 898-4366: Prefabricated components - wing attach assembly, nosegear machined parts, control system components, fuel caps, engine mount, rudder pedals. Catalog costs $2.

FRED JIRAN GLIDER REPAIR, 6 Mojave Airport, Mojave Ca 93501, (805) 824-4558: Prefabricated components, cowling, fuel tanks, wheel pants, maingear & nosegear struts, strut cover & nosegear box. Send 9"x12" SASE with 4-oz postage for brochure

THE AIRPLANE FACTORY, 7111A Brandtvista, Dayton, Oh 45424 (513) 845-9872 or 233-7754 - Canopy. Send SASE

H.C. COMMUNICATIONS, Box 2047, Canoga Park, Ca 91306
(213) 882-0422. Custom COM & NAV VHF antennas.

Special Performance Wing Gross Weight 1700 lb

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh 72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA SAE, AOPA, AND AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION.
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.

AIRCRAFT SPRUCE & SPECIALTY CO. 201 W. Truslow Box 424, Fullerton, Ca 92632 (714) 870-7551
VariViggen spruce kit, plywood kit, hardware, all aluminum and fiberglass. Catalog cost $3.

KEN BROCK MFG. 11852 Western Ave., Stanton, Ca 90680. (714) 898-4366.
VariViggen prefabricated components: all machined parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave., Dayton, Ohio 45424. (513) 845-9872
VariViggen plexiglass canopy

BILL CAMPBELL Box 253 Phelan, Ca 92371
VariViggen brackets and fittings.

MONNETT EXPERIMENTAL AIRCRAFT INC., 955 Grace St Elgin, Ill 60120 (312) 741-2223
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48707

VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS 4102 Twining, Riverside, Ca 92509
VariViggen welded nose and main landing gear. 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, Co 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8" x 10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air Mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook i including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues starting with CP#19 are mandatory for those with VariViggen under construction. Identifies new material sources as they become known. Published quarterly. Price - $4.75 per year first class mail. $6.50 per year air mail overseas. Back issues, $1.00 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the part several years. It covers the entire airplane, including the engine installation fuel system, and not only covers the original standard wing in both aluminum and foam an fiberglass composite, but it also includes the composite S.P. wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65 cu inch size. 555-sq wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines) Price - $475 first class mail, $5.50 air mail overseas.

THE CANARD PUSHER No 22 OCT 79

Published quarterly (Jan, Apr, Jly, Oct) by
RUTAN AIRCRAFT FACTORY
Bldg 13, Mojave Airport,
Mojave, Ca 93501
(805) 824-2645

U.S. & Canadian subscriptions	$6.75
Overseas (AIRMAIL)	$8.75
Back Issues	$1.50

Note! Price increase for the Canard Pusher Newsletter. This is due to the higher costs of the paper, printing and builder support. This is our first increase since CP# 1 in 1974. If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 22. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 22. If you are building a VariEze from the 1st Edition plans you must have newsletter 10 through 22. If you are building a VariEze from the 2nd Edition plans you must have newsletter 16 through 22. A current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 9:00 to 12:00 and 2:00 to 5:00 on Monday through Saturday. If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply. RAF Activity since the July newsletter has included developmental tests on the Long-EZ, flyins to Oshkosh and Columbia and builder/flyer support. The Defiant program is inactive, awaiting financing.

COMPOSITE WORKSHOP - VARIEZE, VARIVIGGEN & QUICKIE A construction - composite seminar will be held at RAF, Building 13, Mojave Airport, Mojave, Ca 93501, on November 24th. 1979. Since construction methods are similar, we are doing this jointly with Quickie Aircraft Inc. There will be flight demonstrations of the Quickie, EZ, Long-EZ, VariViggen and Defiant, between 10am and 11am. Lunch will be arranged from 11 to 12:30 and the workshop will run from 12:30 to 5pm. Builders are encouraged to bring parts, particularly if you have a part that you are unsure of, bring it so that it may be inspected, or used to educate other builders. Mojave Airport is a two hour drive north of Los Angeles on Highway 14: 25 miles on the 355 degrees radial from Palmdale Vortac. Bring folding chairs if you can, wrap up warm, it can be chilly at Mojave in November.

OSHKOSH 1979 - All of us at RAF flew to Oshkosh this year and had an enjoyable trip. We took two new aircraft - Long-EZ and Defiant, also Mike and Sally's VariViggen plus a Grumman Tiger. Due to an "off the cuff" comment to Jack Cox last spring we found ourselves committed to a non-stop Mojave-Oshkosh flight with the Long-EZ - Defiant. We were also scheduled to fly in the opening day airshow, so why not take off from Mojave to do it? After all, there's no arrival traffic at airshow time! So opening day we fueled up the airplanes, put three people plus baggage in the Defiant and took off on our 1780 mile trip. The flight was beautiful - excellent weather and good winds. Because we didn't know how long we would orbit to wait our turn in the airshow the Defiant made a refueling stop at Laramie Wy while the Long-EZ, not wanting to wear the tires unnecessarily, orbited over-head. We arrived at Oshkosh after 9.9 hours flying time (Long-EZ) and found we had to orbit about an hour for our slot in the airshow. Mike Melvill, who flew out two days before, joined us in the orbit and we did our three ship routine before the largest crowds ever at Oshkosh. Average speed for the Defiant/Long-EZ on the trip was 180 mph including the Laramie stop (189 mph stop not included). The Defiant burned 11.2 gal/hour, Long-EZ 5.4 gal/hour. Average tailwind was about 10 knots.

All three of our aircraft flew numerous times during the week in the airshow, fly by pattern and demos. One afternoon EZ pilots literally saturated the fly-by pattern with VariEzes. The Long-EZ flew, after the non-stop from Mojave, two airshows, a demo, a trip to Fond du Lac and a practice LBF lap and still had two hours of Mojave fuel remaining!

It was certainly exciting to see 41 VariEzes at Oshkosh. However, the icing on the cake was when the Grand Champion Custom Built award went to a gorgeous Canadian VariEze built by Norman Ross. See the October 1979 Sport Aviation magazine for an excellent article on Norm's airplane written by Jack Cox. Incidentally Norm also won the Grand Champion prize at the Tullahoma Flyin in Tennessee.

The following are those who attended the 1979 Oshkosh event:

* These pilots did not register at Oshkosh.

LBF RACE 1980 - We are planning a VariEze class within the LBF competition. (see October 1979 Sport Aviation). The VariEze is not designed as a race aircraft and is thus not competitive enough to win the LBF. However, a class for just VariEzes, with its own separate award/prize would be appropriate, competitive and fun. We are suggesting that EZ's enter under the single place rules rather than two-place so they do not exceed gross weight limits. They would thus compete with each other for a prize awarded to the best three category (L, B & F) performance for an EZ. See page 23 December 1978 issue of Sport Aviation for complete race rules.

We are looking forward to a lot of VariEze participation next year so start planning now. The only rules (besides the LBF rules) is that the structural materials and external shape/size of the airplane be per VariEze plans. Clean up items like wheel pants, fairings, etc are legal. Any engine is legal. We are working on a sponsor for the prize money and will report on this in CP 23 or 24. The following is a list of those EZs that have flown since CP #21. If you know of someone who should be on this list, contact us so they are included should an emergency safety advisory be necessary.

Bill English	Houston	Tx

VARIEZE HOSPITALITY CLUB FLYIN - A total of 18 Airplanes flew into Columbia, Ca over two day period, 20 & 21 of October. Unfortunately it rained Saturday, but was perfect all day Sunday. The EZ from the farthest south was from Chino, unfortunately none of the guys from San Diego made it, due to bad weather. In fact, if weather had not been a problem, there was a potential of around 30 VariEzes flying in. The Defiant, VariViggen and Long-EZ flew in from Mojave. Don Shupe made up a few awards, Ed Hamlin - for Best builder support. Les Faus - for giving the most back-seat check-out rides and most hours (100 and 475 hr. t.t.). Bruce & Bonnie Tifft - for Super Flyin coordinators. Dick Rutan - for a "Reluctant" Aerobatic Instructor. Everyone had a great time and all were in favor of doing it again soon. Probably January or February, time and place, not decided.

VARIEZE FLYIN, GAINSVILLE, GA - The "Real" George Scott of Cumming, Ga, organized a flyin over the weekend of 20th & 21st October and had six VariEzes fly in. Three wards were given, Bob Woodall - the Longest distance award. Robert Vaugn - The best overall and the best interior. Jeff Rose - the spot landing contest.

VARIEZE OPERATOR EXPERIENCE - We received many favorable comments about this section of Newsletter 21, so we will plan to make it a regular column. Bruce and Bonnie Tifft - "Here's a fun trip for a Eze owner. You leave on Friday - spend Friday night and half Saturday at the Hollister Flyin with eleven other Ezes. Then we left with three other Ezes (Hamlins, Shupes and Les Faus) and flew to Auburn for lunch. We spent the night at the Hamlins. Late Sunday afternoon we flew over to

Mendocino but found it was fogged in - so we proceeded to Napa for a late lunch (San Francisco area).

Early Monday morning, the Shupes left for Los Angeles and we proceeded north on our way to Paco, Washington. Flying over country like Mt. Shasta and Crater Lake was certainly a thrilling experience. We spent the week with relatives in Pasco - giving rides to the nephews and to a very nice hangar owner who gave us a corner of his hangar for the week - you know how we can squeeze in. We participated in the Blue Skies fly-in the following week-end and did a few fly-bys for the spectators. The Shupes and Hamlins stopped for Saturday evening and then were off Sunday on their way to a Canadian vacation. Sunday morning we headed for Mariposa and then on home Monday.

The trip put 18 hours plus on our Eze which is the longest single trip we have had in our airplane and loved every minute. Perfect weather and perfect Eze performance made for a fun and inexpensive trip. We have total of 131 hours on the Eze now and are looking forward to many more enjoyable excursions".

The "Real" George Scott - "Interesting problem flying a VariEze cross country - I was east bound level at 5500 ft. Another aircraft appears to the right also east bound at the same flight level on a path that will cross slightly behind us. He thinks we are going backwards and since the aircraft to the right has the right of way he turns to the right to pass behind us! I'd sure like to hear his version of what he thought he saw and the evasive maneuver that followed!"

Larry and Janet Lombard - "just a short note in appreciation for the follow-up on the fuel contam. problem. Fortunately, our EZ shows a clean bill of health. We flew the trek to Alaska via Alcan and had a wonderful vacation. We stayed with Tom Kuffels, Fred Kellers and fished a lot. Those folks up there are Great people. We flew the 2600 plus mile trip (one way) on about $100 fuel and averaged 155.8 mph. Our longest leg was 770 miles at 4.45 hour and (with one hour reserve) Janet didn't show too many signs of fatigue. We were a tad over gross though - - - about 1130 for take off, really makes that C-85 grunt. We had many requests for buzz jobs by Canadian towers . . . . and they wanted it in tight over the ramp, not out over the runway. . . . very curious people about the EZ. Thanks again."

Dick Woods/Bobbi Cohen - "EAA Chapter 62 held their annual flyin at Hollister, Ca on July 13 1979. Each gal was asked to bring a cake for the dessert part of the Saturday night banquet. We've got so many VariEze's under construction in the chapter that Bobbi decided to contribute one of her own - an edible variety. The folks in charge of the dinner decided it looked too good to cut, so they planned to award it to the Grand Champion of the show - Larry Lombard's beautiful VariEze! Rather fitting, don't you think. (And we all did get to eat the cake finally on Sunday at a cook-out at Reid-Hillview airport). Here's a photo of the vanilla "VariEze". (pg 11)

Otto Schimmel - "Enclosed are pictures of first flight which Dick Rutan flew in June 1979 at Mojave, Ca. N9036G, VariEze was built by George Gilmer, age 73 years young. Three years total time at Santa Paula airport, Ca. Total cost was about $3600. George made almost every part. Wing fittings, wheel and brake system, throttle quadrant etc.

He advises all builders, if Burt gives a measurement or method there is a reason. He believes that in all his years the VariEze and plans are the best there is. George started flying in 1929. But had one big thrill when Mike gave him a ride in his VariViggen".

Wilma Melville - possibly the only woman VariEze pilot, Wilma Dasche-Melville, has completed her 100th hour in the airplane which she and her husband John built over a period of 1 1/2 years. A P.E. teacher from the Torrance, Ca school district, she included the EAA Oshkosh fly-in in her schedule. Note: John built the EZ with Wilma's help, but he is not a pilot and is thus confined to the back seat!

Helma Hamel - "last May, after I heard my husband Ellsworth groan over the changes in the last newsletter I made up the enclosed "poem". I wanted to send it to you, but Ells thought it was too corny. Well, I just mailed to you the announcement of Ell's first flight in VariEze N235EH and I decided to mail the "poem" too. You still might get a smile out of all that corn. It was a tremendously scary and exhilarating moment, when Ells started climbing. There is nothing in my life that can compare to the shudder and thrill I felt, not even the birth of our first child.
First the announcement -

She Flies.

1976
Summer: A dream, a wish, and a gigantic set of "How-to" plans.
Autumn: We take lessons, place our order with the stork and ready the nest.

1977
Winter and Spring: Ouch! What labor pains! It takes 6 months for the whole egg to arrive
Summer and Autumn: We are hatching. Every spare minute we are hatching.

1978
Winter: We have to keep the egg warm through the harsh Pa. winter, so we build an incubator.
Spring: Still hatching.
Summer: There she is: a complete bird, ugly, green and blotchy, but her wings are in the right place.
Autumn: We care for and feed an insatiable bird. She sure can swallow the dough.

1979
Winter: Her nervous system is maturing, her reflexes look good.
Spring: The great metamorphosis: The blotchy green fledgling changes to coal black, then to shining white. But Dr. Rutan orders corrective surgery for her and all of her species.
Summer: She is whole again, and she has a voice after some hiccoughs and sputtering she purrs.

AUGUST 13 She is flexing her wings, she is airborne.
IT'S A BIRD! IT'S A PLANE! IT'S VARIEZE N253EH!

Now the Poem -

St. Peter's Lament

St. Peter shook his haloed head and scratched his grizzled beards
I don't know what to make of this; it's positively weird.

Each ninety days a monstrous moan floats upward to the skies,
A sound so woebegone and sad, the angels wipe their eyes.

It starts to build around L. A., and by the second day,
It echoes and reverberates across the U. S. A.

I strain to glean from all this din just one revealing word,
But what the voices clamor for seems freakish and absurd.

They wailed of "worm gears", shrieked of "cuffs" until I plugged my ears.
They howled for "rod ends" and such stuff, and now it's "landing gears."

I hear some fellow is to blame, some airborne desert chief,
A real designing so-and-so, who thrives on all this grief.

He tinkers, toys and tabulates and smells of gasoline.
He rules a back room printing press, an instant-gloom machine.

He mails a little quarterly, the source of all distress
From desert hide-out to the world, it's called THE DOOMSDAY PRESS.

And every man who reads his news will instantly be changed.
Some grow morose, some snarl and snort, some end up quite deranged.

Some yells "The ripper strikes again!" Some throw epoxy fits.
Some sobs "By Jove it's VariHard." Some drown their grief in Schlitz.

I yearn to zap that scoundrel now. I'm certain of applause.
But strange enough some heavenly host have rallied to his cause.

The Life Extension Service claims, because this fellow cared
A dozen men, who had been marked for reaping, have been spared.

The cherubs plead the poignant fact, that he's an ace, he flies.
Can I think ill of any man who reaches for the skies?

They've seen his wings; they call him kin; that sways me, I admit,
For flyers are a noble breed, a joy, and full of grit.

Is he a rogue or lily white? I only wish I knew.
I hear he's looking for new fields and brand new things to do.

He says - this caper leaves me stunned, his brashness I deplore -
He just designed a better wing for my own angel corps.

LONG-EZ N79RA UPDATE - Today the Long-EZ has 102.4 hours, a new set of wings with different winglets, and longer ailerons. The standard VariEze wings did not work well and were abandoned after Oshkosh. We burned the midnight oil and designed and built a new rear wing system. The 23-degree L.E. sweep, Eppler airfoil, and wing attachments are similar to the Defiant. Improved foam core jigging and glass lay up methods were developed. The 42% increase in wing area was made with very little weight increase. The wing spar and center section spar overlap and are connected with three bolts in shear that allow an EZ wing incidence change with shim washers. We are very satisfied so far with the performance. We have excellent stall characteristics with a wide departure margin. We don't anticipate ever needing wing cuffs. The aircraft is very stable at full aft cg. This cg limit is reached with a Lycoming 0-235 with starter, alternator and fuel pumps and a 125 lb pilot - no ballast. The approach and landing speeds are 5-6 knots lower than a VariEze. Deck angle is low enough that the over-the-nose-visibility is excellent at touch down with full aft stick! Useful load is increased over a VariEze, resulting in a single-place range of 1400 miles and two-place range of 800 miles. However, we're still not finished. At the new lower takeoff and landing speeds the rhino rudder effectiveness is inadequate which may force us to revert to the conventional winglet-mounted rudders (I see some of you smiling). We are so encouraged with the new wings and overall flying qualities that we have applied to attempt a world class-closed course distance record this fall. Please understand the LONG-EZ is not finished - its still in flight test and more things could change. But we are very close to a design freeze. Complete details on the Long-EZ and plans will be in CP 23. Please wait further questions till then - we need to get the work done!

TECHNICAL CORNER - We will plan to make the Technical Corner a regular feature of the Newsletter. VariEze materials tested to support Space Shuttle - NASA's Dryden Test Center recently flew an F-15 fighter with a wing addition constructed of three pound urethane foam skinned with four plies BID/Epoxy. These wing additions were subsequently covered with space shuttle tiles, to test their ability to withstand loads expected during reentry. The bare BID/foam additions were flown to 1.5 times the max expected dynamic pressure of the shuttle - 1100 lb per square foot, at 1.4 mach, 660 mph indicated speed. This is a dynamic pressure of nine times that of a VariEze at red-line speed!

The equivalent flat-plate drag area of an entire VariEze is less than 1.5 square feet, or roughly speaking, an EZ has the same drag as a square flat board 14 inches on a side. With this small amount of total drag, adding drag-producing additions will have a large effect on the aircraft's performance. For example, a cross-over exhaust system will slow the cruise speed by 10-15 mph, due to the drag produced by the blunt bumps required on the cowling. This increment has been verified by everyone who has made this exhaust change. The bumps also cause turbulence that increases prop noise.

Moisture change - moisture on a wing from rain will effect its lift. This effect is small on a conventional aircraft, ie, the Grumman Tiger descends 500 fpm if untrimmed entering a rain shower, but is easily trimmed out. A Canard aircraft generally has a much larger trim change in rain because its high lifting wings are located far apart. We do

not fully understand the reasons for this, but the following characteristics exist for most VariEzes: if a trimmed

---

EZ enters light moisture or light rain it will climb, requiring about 1/2 lb to 1 lb push to maintain level flight. In heavy rain, most EZs trim nose down, requiring a mild aft stick pressure to fly level. The trim change varies with speed, being barely perceptible at 70 knots and higher as speed is increased. One EZ flyer reported a heavy aft force required (15 to 20 lb) when making a 150-knot (172 mph) descent through a heavy rainshower.

We often hear the following comment from EZ pilots who have just flown their airplanes, "my speed is low, I set the power for 2650 rpm (75% power) and only get 166 mph true". You are not at 75% power, just because you have set the rpm for that power on the Cessnas you are used to flying. Remember, the EZ has very wide speed range for a fixed-pitch prop. To get adequate take off performance, the EZ has to turn high rpm at 75% cruise. Refer to the following chart for a clean 0-200 EZ with Ted's prop and wheel pants. At 8000 ft and 2650 rpm you are generating only 49% power (a good economy cruise). To get 75% pwr at 8000 ft you have to use full throttle and turn 2990 rpm at a TAS of 193 mph. We generally do not cruise at 75% - we prefer 60% or less to conserve fuel and reduce the noise level. 60% gives a TAS of 178 mph and fuel flow of only about five gal/hour at peak EGT. Static rpm - if you have a static rpm of less than 2450, with the 0-200 or 0-235 engine, you will have poor takeoff performance, due either to too much prop or a sick engine. Be sure your tach is calibrated. The hand held Heath kit thumb tach works well. Can even be used in flight, just point it back from inside the cockpit **GRAPH OMITTED**

FLYING HINTS - Check your aileron hinges for wear (particularly the inboard hinges) and lubricate with a dry graphite lube. Some builders have reported wear that stopped when lubricated.

Clarence Langerud reports solving his engine cooling problem. He added a 5" long 2" wide strip of .032 alum to the front baffle and bent a 1/2" radius on the center and aft baffles (see dwg) **SKETCH OMITTED**

For those who fly in rain and have had prop tip damage, Bruce Tifft of B & T Props has developed a wood prop with a hard rubber or urethane leading edge, that has proved impervious to damage at full throttle in very heavy rain. Note that B & T Props address was printed incorrectly in CP #21 and should be - B & T Props 8746 Ventura Ave., Ventura, Ca 93001 (805) 649-2721

George Scott suggests a neat way to improve your proficiency before flying your VariEze. George used a Cessna 172, sat in the right seat, reclined the seat to stimulate the seating position of the EZ, then go out and practice some high speed taxi, runway flights and landings. Do take a safety pilot with you in the left seat!

FLIGHT SAFETY BULLETIN - A VariEze experienced a forced landing due to engine failure caused by collapse of the induction hose. The owner had

not safetied the wire and cord as per the instructions and drawing (Sect II A page 14 - 1st Edition, Section IIA page 17 2nd Edition, Section IIC page 13). If these are not safetied the cord can unwind, allowing the wire to twist and lie flat. Inspect your induction hoses. If they are not safetied, ground your aircraft until corrected. This bulletin was included in our fuel compatibility questionnaire.

Flight Research Inc, reports a service failure of the strut support tab of their VariEze R/H muffler. Their recommendations:
1. Inspect attachment tab regularly
2. If tab has failed, weld on larger and heavier gauge tab prior to next flight.
3. If no certified welder is available, send R.H. exhaust unit to Flight Research Inc., for free repair.

BUILDER HINTS - Engine baffling - Lyc 0-235. When you cut your baffle material out according to Section IIC errors exist leaving the aluminum pieces short in some areas. Leave the Baffles about 1" too large, then trim to fit cowl. Leave 1/2" gap between the edge of the aluminum baffle and the cowling on trim before installing the rubber.

John Harris recommends a large farrier's horse shoe hoof rasp for shaping foam, roughing glass etc. We have found an excellent substitute for sand paper in the form of a Disston Abrader (course #401C) available at most hardware stores. Aircraft Spruce is now stocking the 401C. It is a long-life abrasive tool that's excellent for shaping curved fiberglass edges.

We recently tried a new product that is a big time saver. It is an acceptable substitute for dry micro in the finishing process. Stitts micro-putty (MP 1100) available from: Aircraft Spruce and Wicks. This is a polyester - based material similar to Bondo, but 1/3 the weight, cures in a few minutes and works and sands similar to dry micro. Caution: do not use on blue foam.

Steve Briggs found an excellent method of setting wing incidence. While wings are still in the jig, on the table (both root and tip water lines level) bondo a Stanley line Leveller (available at most hardware stores @ approx. $1.60 each) to the outboard edge and parallel to the buttline of your WA-1-1 wing fitting. Check that the root and tip water lines are level and that the Stanley is level before removing wing from jig. Use this level later to adjust wing to center spar (replaces the bondoed board, from CP #12 page 8).

A finger tip saver when finishing featherfill through final color coat, use a sponge with sanding material bonded to it, sold at hardware stores as Quicksand/Auto Wetdry, Medium/course.

Nat Puffer sends this idea to check your epoxy balance for accuracy. Simply put 20 nails in the hardener cup and 100 nails in the resin cup, or for the new Safe-T-Poxy system, 43 nails and 100 nails. Nat says it works great.

For those of you having difficulty drilling the 8 holes in each wing fitting, F.J. Wells recommends a Stanley drill Guide #04-413 glued to the WA 1 fitting with beads of hot melt glue. Produces excellent, perpendicular holes. Jake Bach reports that he modified his Michael's

Engineering ratio pump per CP 21 and got 39-100 instead of the desired 43-100. He then switched the pivot from the left to right (hardener piston greatest distance from pivot) and that put him right on the money. We don't know why his pump is different than ours, but we caution you to be sure to check your ratio if you modify your pump - pump into two cups and check on a balance scale.

Don Yoakam reports that if you update from old to new style Rosehan brakes, be aware that toe-in may change. The backing plates are rough castings and may not attach in the same position.

Sam Cochran made a carb heat valve using two Campbell soup cans covered with two plies of B.I.D. His has over 100 hours with no wear or defects.

CP22, Page 4

Solution to "back off" of roll trim servo. Some EZ flyers have experienced their roll trim tab being forced toward neutral due to airloads in flight at high speed. Garth Shearing, Canada, a VariEze builder has pointed out that the servo cannot be backed up if it is shorted across the motor terminals. Yes, I didn't believe it either, but it's true - try it! The following circuit can be used, which requires two DPST switches - one for left trim, one for right. This wiring will provide a short for the motor at idle, locking it in position and provides protection from both switches being operated at the same time. **SKETCH OMITTED**

The fuel tank vent can be covered in a steep climb and result in some venting of fuel. To avoid this (new construction only) position the vent tube 15" forward of its position shown. Enter the tank at the plans-position then route the tube forward - this avoids conflict with canopy latches.

GOOD NEWS

Many of the VariEze operators have experienced inaccuracies in the designated engine instruments particularly the Tach. Because of this, on the recommendation of Jim Proctor of Shady Cove, Oregon, we installed a completely different line of instrumentation in the Long-EZ. This new instrumentation has performed very satisfactorily. We feel these are superior to what have been recommended before. Example- this new Tach runs independently of the magneto switch, using a very small sender that screws right on to the engine tach drive. This small sender will run two tachs. We were impressed with its accuracy and reliability. Our calibration of all these gages proved them to be accurate. (However, any instrument should be calibrated prior to use). The Vendors are on line and this new instrumentation is being stocked by Aircraft Spruce and Wicks Aircraft Supply. Specific gages should be ordered as follows:

GAGE	PART #
Carr Electronic Tachometer	206
Carr Electronic Tachometer Sender (includes adapter kit)	207
Oil Temp. 120 - 300 degrees F	VDO 310-014
Oil Temp Sender	VDO 323-057

Oil Temp Wiring Kit	VDO 240-023
Cyl Head Temp 100-600 degrees F	VDO 310-909
Cyl Head Temp sender	VDO 323-701
Cyl Head Temp wiring kit	VDO 240-701
Volt Meter 8-16 volts	VDO 332-044
Volt Meter wiring kit	VDO 240-024
Engine Hour Meter	VDO 331-011
Engine Hour Meter wiring kit	VDO 240-024
12V Chronograph (clock)	VDO 370-022
Oil Pressure 0-150 psi **	VDO 350-044
Oil Pressure sender	VDO 360-004
Oil Pressure wiring kit	VDO 240-023

** This gage can be wired to include a low pressure warning light. We have this in Long-EZ.

SAFE-T-POXY - We have been using Safe-T-Poxy extensively here at RAF over the past 6 months. The new Long-EZ wings use Safe-T-Poxy. During this period the temp's were warm 80 degrees - 100 degrees, and the epoxy worked beautifully. However, lately with temps dropping down into 60 to 70 degrees the Safe-T-Poxy wets slowly. This can be solved by placing a light bulb under the ratio pump to get the temp of both the resin and hardener up around 80 to 90 degrees.

When mixing micro balloons with Safe-T-Poxy, only 3M B23, 500 (available from Wicks and Aircraft Spruce) glass balloons should be used. If you use Quarts Q-cell balloons, due to alkaline, the cure will be delayed, depending on temp as much as two or three days. Although it does ultimately cure, and is structurally ok, this much delay, particularly in finishing is not acceptable.

Safe-T-Poxy is now available from both Wicks and Aircraft Spruce, and is excellent in all respects. All physical properties are equal to or exceed those of RAEF and S. Safe-T-Poxy particularly excels in fuel compatibility and low moisture absorption. We continue to receive reports that Safe-T-Poxy has definitely solved the health problems of many people that are allergic to normal epoxies.

ROTORWAY RW-100 UPDATE - Our latest information is that the prototype engine has been taken out of the VariEze and an aggressive test cell development run is underway. We are encouraged to hear that their advertising blitz has been put on the back shelf and the major effort is now on engineering development. We are also gratified to hear that the cam/valve overlap has been changed to allow hand propping. Without starter and ring gear the weight may be within VariEze limits. We are encouraged that the development is continuing and the performance and reliability will be determined. A new 100 hp aircraft engine is certainly needed. We wish B.J. Shramm all the success in his effort. We will continue to monitor this program and will test an engine when appropriate.

HIGH COST OF ENGINES - We have been hearing a lot of complaining about the high cost of engines. True, a new engines' cost is approaching ridiculous. But, if you can find a partially run out engine it can be more of a bargain. The Long-EZ has a Lycoming 0-235 that had 1400 hours and it cost us $1500. It was installed without modification or repair. The Lycoming has a 2000 hour TBO so we can expect 600 hours

flying on this engine (3-4 years). When it is "run-out" - 2000 hours in 1982 it will still be worth what it cost us. Thus, its truly a low operating cost engine (zero $)! This newsletter lists a 400 hour C90 at $2800. If you run it out (1200 hour left) then sell it for $1500 you have spent $1.08 per hour for engine. If you buy a new or newly over-hauled engine at the high going cost, and sell it for run out cost, you will spend $2 to $3 per engine hour. Remember the majority of you will take years to put a few hundred hours on an engine. So, consider a 1/2 or 3/4 run out - its still a bargain. Run an add in Trade-a-plane (Crossville, Tn 38555), it works!

HOMEBUILT PROPELLER - We have just reviewed the plans for a home built VariEze propeller by Larry Weishaar and have tested a homebuilt prop built from his plans. The plans are a true manufacturing manual, very detailed. The 32 page photo-illustrated document contains a full size drawing and station templates and a considerable amount of technical information from cutting down the tree to the finished balancing. With these plans I believe anyone could build an excellent prop. But what about performance? We have in the past used Teds 56 x 76 prop as the standard because it gave about the best performance of any we have tested. Again we were impressed for we found Larry's prop to be every bit as good as Ted's and possibly a slight bit better in cruise. The sample prop was quiet and smooth and seemed to scavenge the engine cooling air better, as the climb CHTs were down 20 - 30 degrees F. We are happy to give Larry our wholehearted endorsement and congratulations for an outstanding set of plans. A real bargain at $17.50, they may be purchased from:

Larry Weishaar,
1924 No 6th Street,
Springfield, Ill 62702

DISTRIBUTOR REPORT

Aircraft Spruce and Wicks.
Both report VariEze kit and materials are all in stock. Partial or complete kit orders are being processed within a few days. Customers can pick up a complete kit with a one week notice. Both distributors currently stock RAEF, RAES and SAFE-T-EPOXY.

Ken Brock Manufacturing.
Ken has been doing an excellent job in stocking adequate quantities of the EZ components allowing prompt delivery. Ken now has a good stock of EZ prop extensions, axles, wing fittings, welded parts, crank nose gear assemblies, spinners, etc. Ken's spinner is a completed item, not a kit. It requires only the prop cut outs to install.

The Airplane Factory.
EZ canopies and Viggen canopies are in stock and being shipped promptly. TAF offers a 1/2-price replacement should you break your canopy for any reason in the first three years.

Fiberglass Parts.

The vendor for the VariEze fiberglass parts notified us last July that he was modifying his business operation and would discontinue manufacturing the nose and main gear parts, but would supply them until we could locate another source. At that time we decided that, since tooling for the main gear was wearing out, we would not arrange for the new manufacturer to produce this same item. Instead, we are developing a new gear, which is 40% stronger and made with an improved process. This gear is designed specifically for the Long-EZ, which has a gross weight 24% heavier than a VariEze. We plan to have only this new gear produced by the new vendor, and use it on both the EZ and Long-EZ. It is three to four lb heavier than an EZ gear. We have also developed an improved main gear attachment design which is now being tested on the Long-EZ. Once the tests are done and the new gear is in production we will make the gear (and gear attach design) standard for both the Long-EZ and new-construction VariEze.

Last month the fiberglass vendor informed us he would no longer produce any of the VariEze parts, after clearing his present backlog. We are busy setting up the details for a new vendor to produce the cowlings, nose gear cover, and nose wheel box. Unfortunately, due to time delays in transfer of our tooling (the old vendor needs to finish his backlog), there will be delays in the availability of these parts. We are taking this opportunity to address some improvements in cowling shape to reduce aerodynamic drag and improve cooling. We should have complete details on the new parts in CP #23. Availability of all the new fiberglass parts is expected by mid December. Contact us after that date if you are needing parts before CP #23. We regret that this condition will result in delays for some of you. However, once these parts are in production they should be off-the-shelf, a considerable improvement over past availability.

In setting up the production and distribution of fiberglass parts with the new vendors, we want to be sure to have an arrangement that provides good service to VariEze customers. We would appreciate hearing feedback from those who have dealt with the old vendor so we can assess if any improvements are needed in the areas of pricing, availability, customer service, etc. Please let us hear from you.

FOR SALE Because of an engine change, I have an unused Cassidy prop 58" x 67" suitable for a Lyc. 0-235 with an SAE #1 flange 4 3/8" bolt circle diameter.
Dewey Straley,
488 Fairfield Ave.,
Gretna, La 70053

Lyc. 0-235 for sale.
W.E. Clark,
116 West University Pkwy
Balto, Md 21210
(301) 889-5092

Lyc. 0-235-CI for sale $2200
Al Kramer,
Sal Val Aviation
Van Nuys Airport,
Van Nuys, Ca.

Dan Lee has found some small (1.15" dia) volt meters and ammeters, to check solar panel charging.
100 c Volt meter 0-15 DCV - approx $30
100 c ammeter 0-500 DC MA - approx $26.50
Available from - International Instruments
88 Marsh Hill Road,
Orange, Cn 06477
(203) 795-4711

Lyc. 0-235-L2C complete with mags, carb, starter and alternator and fuel pump. 460 hrs. T.T. since new. Crankshaft flange bent .008" - $2900
Bill Aronson - (805) 256-2200

David Turansky, - - - - - - David has an excellent C.P.
433 Herkimer Street, index, CP 10 to CP
Buffalo, N.Y. 14213 21 for $3.00

Continental C-90-16L 400 hr since new, $2800
Dick Rutan at RAF (805) 824-2645

Both Wicks and Aircraft Spruce are now stocking two excellent canopy seals. One, K-Strip is shaped **SKETCH OMITTED** (Wick's Part # 44-57240) works great, and the other, P strip shaped **SKETCH OMITTED** also works very well. These are sold by the foot and although they have an adhesive backing, you may need to supplement this with RTV or silicone.

Posters. RAF has a beautiful poster of our three ship formation - Defiant, VariEze and VariViggen (see back cover of this new newsletter). This photo was shot by Budd Davisson. The poster is color, 18" x 23" and quality suitable for framing. They are available for $2.75 each or two for $5 at RAF. Add $1 if ordering by mail to cover mailing tube and 1st class postage. Specify plain or autographed.

Defiant Film. Ferde Grofe's Defiant film has received some excellent reviews. General Aviation News - "Defiant is one of those rare short documentary films which left us wanting more" - - "delightful film experience". If interested in purchase or rental send SASE to A.V. Library, 18139 Coastline Dr, Malibu, Ca 90265

Survival Kit
Ray and Nova Cullen (see CP 21 Page 2) 1116 6th Street, Tillamook, Or 97141, have developed an excellent accessory for the VariEze. It is a custom light weight survival kit designed to double as an additional thigh support for the rear seat. These are well done and we plan to install one in our airplanes. Contact them for price and availability.

VARIEZE LOSS-OF-CONTROL
We have just completed another series of flight tests on N4EZ to test its departure (loss-of-control) resistance. What prompted this is reports from two VariEze pilots in Texas that they experienced a

partial or full snap roll at about 80 knots. These occurred below pattern altitude and fortunately the pilots managed to recover in time to avoid an accident. The maneuver was described as follows: Full aileron and partial rudder steady sideslip, then full rudder was applied which caused the airplane to yaw excessively and abruptly roll, experiencing negative g. Recovery with neutral control was prompt, but several hundred feet of altitude was lost.

The most surprising thing about these incidents to us was that control was lost at such a high speed - 30 knots above stall. Reinspection of our stall/spin test data and the NASA tests indicated no susceptibility to departure. We then initiated a new test program to investigate this. Dick performed full rudder sideslip with N4EZ at all speeds and experienced no departures. Concentrating on the 80-knot speed range he then aggravated the yaw with abrupt rudder inputs while in a rolled attitude. On one of these he experienced a departure - a roll off in the direction of the slip. He then tried to repeat the maneuver and could not get a departure in over 20 attempts. We then adjusted the aileron and rudder rigging, moved the cg aft, and repeated the tests. Dick found that by learning a specific technique he could cause a departure nearly every time, if speed were above 75 knots and an excessive sideslip angle were generated. The departure generally consisted of an uncontrolled roll away from the rudder input direction. Recovery with neutral controls was prompt. However, on several of the maneuvers the yaw angle was extreme at departure causing a massive stall of the winglets and blanking of the upstream wing. The airplane then yawed past 45 degrees, abruptly rolled, and entered a 1 to 2 turn inverted incipient spin. The airplane always promptly recovered with neutral controls. If aileron or rudder were applied for recovery it could cause a further "snap" departure and delay recovery. Altitude loss on the worst of these maneuvers was as much as 1500 ft.

Why did we not find this departure when we did the original tests and the tests with cuffs in 1978 (CP #19)? The most probable reason is that most of those test were done at high angle of attack (full aft stick) which was thought to be the worst case. However, we have found that at lower angle-of-attack ie, 80 knots, the rudders can generate more sideslip than at high angle-of-attack, and thus can be powerful enough to stall the winglets in an accelerated yaw maneuver. We were then faced with a decision on what to do: (1) caution pilots that the airplane can be departed when using excessive yaw inputs or (2) fix the airplane to improve its departure resistance. Since we feel strongly that good departure resistance is an important asset and design goal for the VariEze, we set out to attack # (2).

We have always known that the EZ has more rudder power than needed for normal maneuvers - a full aileron steady sideslip at low speeds requires only 60% of the available rudder to hold heading. The available travel is 3 1/2 inches, measured at the top of the rudders trailing edge. We then limited the rudders travel on N4EZ in various increments, 3", 2.6", 2.3" and 1.8". At each increment we flew tests to determine departure susceptibility and the necessary rudder authority for crosswind landings.

As expected, the departure susceptibility reduced as rudder travel was limited. After extensive testing and evaluation by three pilots we have N4EZ's rudder now rigged for a two-inch full travel. With this

rigging, the following characteristics exist: crosswind landings up to a component of 24 knots are possible without tire scrub. The aircraft is not susceptible to departure during any normal maneuver. Thus, we are now recommending a mandatory rigging change to limit the rudders to two-inches of travel.

It must be noted that this may not guarantee total departure resistance. This may vary from one airplane to another, due to expected tolerances in things like winglet leading edge finish and shape, fuselage shape etc. Also, even at 1.8 inch rudder travel, Dick was able to induce a departure by learning an unusual and aggressive combination of control inputs: full left aileron, full left rudder at 30 degrees bank, then at 100 degrees bank abrupt full right rudder. When this was done a departure was possible (not probable) even though the rudder was limited to 1.8 inches.

The important thing to note is that, even though this design is not as susceptible to loss-of-control as a conventional aircraft it should not result in over-confidence on the part of the operator. Assume your aircraft is susceptible to departure until proven resistant during your stall tests with lots of altitude and a parachute. Refer to the plans-changes section of this newsletter for a caution note to be added to your owners manual and for instructions on rigging rudders to two inches.

FUEL/FIBERGLASS COMPATIBILITY - This year at Oshkosh, Nat Puffer had a partial power loss on take off and safely aborted. The cause was found to be a large amount of orange gummy residue in the carburetor. Our concern was that there might be fuel/epoxy incompatibility, possibly due to the high-aeromatic automotive fuel he was using. In August we prepared and sent to all known VariEze flyers a detailed inspection procedure and survey questionnaire, to determine any trends. Applied Plastics (APCO) also conducted an aggressive accelerated aging evaluation to determine if the aromatics used in high octane low lead fuel will deteriorate the epoxy. Results: APCO, RAES & RAEF showed a very slight amount of material extracted from the epoxy but well within acceptable limits. Under normal conditions such as the way VariEzes are used it would take years of exposure to extract even a trace. The new Safe-T-Poxy even under rigorous test conditions was essentially unaffected. Jim Tome ran some tests at a major midwest lab found that the aeromatics in automotive and some aviation fuel 100LL will craze and leach out the hardener in a hardner-rich Lambert lay up and this is probably what happened to Nat. Jim also found that the fuel additive "canned heat" and MEK can dissolve the new Safe-T-Poxy. The problems are with the aeromatics the oil companies are using more and more of. This is explained more in our fuel compatibility AD letter.

Out of the 64 returned survey questionnaires, 52 had no problem at all, 10 reported a trace of gummy substance on the float/mixture needle valve. Several mentioned this could cause the valve to stick, this is becoming a common problem with many other aluminum-tank airplanes using 100LL. One reported a gummy substance in the bowl like Nats. We will be analyzing this sample. Our conclusion is that the RAEFs and the Safe-T-Poxy when properly mixed should not deteriorate when exposed to aviation fuel. However, as a precaution we are recommending routine carb bowl inspection. If you are a VariEze flyer and did not receive our survey on the fuel contamination inspection/questionnaire, then we

don't know you are flying. Write to us giving your N number, name, address, and date of first flight. We will send you the survey and add you to a confidential list. This list will be used only to mail you any urgent flight safety information.

VARIEZE PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe. It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft Do not fly until the change is been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety
OBS	Obsoleted by a later change.
MEO	Minor error or omission

MEO	Sect I Page 11-4	AN 960-4 should be AN 960-416 (2 places)
MEO	Sect I Page 17-11	2" thick top foam piece 12.5" should be 15"
MEO	Sect III Page 2	#12 wire can be #18
MEO	CP #20 Page 5	65 lb fuselage weight should be 72 lb.
DES	Sect II Page 21-4	Route vent lines 15" forward within tank
MAN-GRD	Sect I Page 19-12 Sect IV Page 28	Rudder travel - Mandatory change before next flight. Reduce rudder travel from 3.5" to 2.0". This can be done by cutting the cable and

inserting both ends into a nicopress sleeve to shorten the length. Make fine adjustment with the fitting on the top of the master cylinder. The rigging check takes two people- one in the the cockpit pushing full rudder pedal deflection and one measuring at the top of the rudder while applying a mild aft airload (about 3-5 pounds) on the rudder trailing edge.

MAN-GRD Sect IV Page 30 — Under power plant add "inspect induction hoses for correct safety of wire and cord". Perform this inspection before next flight.

MAN-GRD - Sect IV Page 37.

Correct the CP 21 addition to read "before first flight clean and flush all screens, both carb and gascolator. Remove and clean out carb finger strainer and carb float bowl. Check for a gummy substance on the needle valve. Repeat this inspection each 25 hours for the first 100 hr and 50 hrs there after".

MAN-GRD Sect IV page 19 — Add the following paragraph "CAUTION - Avoid aggravated full-rudder, cross control sideslips at low altitude. The VariEze is departure-free at full-aft-stick stall speed. However, at higher speeds the rudders become more effective and a enough sideslip angle can be generated to stall a winglet. If winglet stall occurs at the same time a roll rate is being generated in the opposite direction eg, full right rudder and full left aileron, the aircraft can depart controlled flight. Departure is evident by an uncontrolled yaw and roll. Recovery is normally prompt when controls are neutralized, however if yaw is extreme, the aircraft may rotate for several seconds and experience negative g. Use neutral controls until recovered (rotation stops). Total altitude loss in an extreme departure can be as much as 1500 ft".

MEO Sect IV Page 7 — Add the following under fuel systems - "do not use fuel additives (such as fuel deicer) unless their compatibility with fiberglass/epoxy has been verified.

VARIVIGGEN NEWS - by Mike Melvill

I flew N27MS to Oshkosh this year and had a super trip, flew in formation all the way there and back with a 180hp Grumman Tiger, piloted by Sally. The Viggen had to be flown at quite a low power settings in order to stay with the Tiger, at ground speeds around 140

knots (162mph). I only burned 7.8 gph average for the whole trip. Not bad for 180 hp.

We flew from Mojave via Las Vegas Nv, Provo Ut, Scottsbluff Nb, Rochester Mn to Oshkosh. The Viggen joined up with the Defiant and Long-EZ for several airshows during the week. From Oshkosh Sally and I flew (Tiger and Viggen) to Indiana to visit family and then via Coffeyville Ks, Tucumcari NM, Abq NM, to Mojave. It was a most enjoyable trip. I put 37 hours on the Viggen, she now has 366 hours and apart from adding 2 quarts of oil she required no maintenance. The only new Viggen flying since CP 21 is a French VariViggen, built as a flying test bed for the Microturbo jet engine. This very beautiful aircraft is powered by two of the diminutive jet engines (same as BD5-jet) located one above the other. The aircraft has only flown a few times, but reportedly is quite fast.

Unfortunately, since CP 21 there have been two VariViggen accidents, see page of this newsletter. Although causes are not known for sure, pilot proficiency still appears to be a problem. You must be current and sharp in several airplanes before attempting a first test flight in any new airplane. Do follow the owners manual to the letter. Do not omit the high speed taxi, and runway flights. If possible, get a checkout in a Viggen with an experienced Viggen pilot. All of you are spending several years and several thousands of dollars; don't throw it all away with careless flight testing.

I have a hunch that several Viggens are almost flight ready. When you are, give us a call, we will be glad to help you with your test program or provide a Viggen checkout. I have only heard from a few Viggen builders, one Bertil Forner of Stockholm, Sweden, (see photo) reports good progress and has the basic airframe complete and is working on landing gear and control system. Russ MacMillan of Abbotsford B.C. Canada, reports that he is progressing slowly but surely, as do Frank Stites of Wayland Ma and a couple of builders in Texas.

VIGGEN BUILDING TIPS - When rigging your ailerons, be sure to set all belcranks at the fuselage stations shown on page 40 (1st Edition) and pages 46 & 47 (2nd Edition). Clamp AB4's and AB8's at the angles shown. The fabricate AB1's to AB10's to fit. This must be done correctly. It is possible for stick to lock over center if the belcranks are rigged at the wrong angles.

EXHAUSTS - The standard VariViggen exhaust system must be tied together and to the crankcase, in order to reduce the possibility of the pipes cracking. This has been in service on N27MS for 120 hours with no sign of a problem. See sketch. **SKETCHES OMITTED**

ACCIDENTS
Since the last newsletter there have been two VariViggen and four VariEze major accidents. An Ohio VariViggen crashed just after making a tower flyby to check an unsafe gear. Ground witness (pilot) reported an object fell off the engine then the engine sputtered and quit. The aircraft rolled sharply left nose pitched up and the aircraft struck the ground in a high rate of sink. The pilot was fatally injured.

Apparently the pilot tried to make a turn back to the runway but due to low altitude/airspeed the aircraft developed a high rate of sink and crashed before the turn could be completed.

A Michigan VariViggen crashed when the builder/pilot over-controlled in pitch just after his first take off in the aircraft. The aircraft was totally destroyed, but luckily the pilot survived with very minor injuries. The initial flights were flown by a qualified test pilot and he reported the aircraft was stable in all three axes and flew "practically hands off". Although the opportunity for a check out was available, the builder/pilot did not take advantage of it.

An Arizona VariEze crashed just after take off on its initial flight. The aircraft was destroyed and the builder/pilot received major injuries. We have requested but not yet received, more details on this accident.

A Florida VariEze crashed when the canopy came open just after take off. The pilot was attempting a 180 degrees turn back to the airport when the aircraft pitched down rolled left and contacted the ground. The aircraft was destroyed, the pilot received serious injuries.

A Missouri VariEze lost power just after take off and received major damage in the ensuing off field landing. The owner/pilot and his new bride were not injured. The engine failure was determined to be water in the fuel.

A Colorado VariEze crashed during landing approach when another aircraft pulled out in front of him for take off. The aircraft was totally destroyed, the pilot received very serious injuries. We have requested but not yet received details on the accident.

The Michigan VariViggen accident was apparently precipitated by the pitch trim change with power change. An experienced pilot made the first few flights on this Viggen and reported it to be "hands off" in all three axes, with good flying qualities.

Without the invaluable benefit of a check out, the builder/pilot made his first take off and was "surprised by the sudden rotation and immediately reduced power". Of course, due to the high thrust line, this caused the airplane to pitch up even more. He then slowly added power, but was probably slow enough to be sinking at this point, and the added power, pitched the nose down, only aggravating the situation. At this point the airplane was diving towards the ground, and as he put it, was as though the bottom of a loop, and he smoothly applied back pressure to pull out, contacting the ground, wings level, but with enough force to virtually destroy the aircraft.

Fortunately, he was not seriously injured, but nevertheless, he has lost a very beautiful airplane, that he worked four years to build. The pitch trim change with power on the Viggen is not extreme, nor abrupt, and is easily controlled. A low proficiency pilot can easily learn to compensate with the stick to maintain the proper attitude. However, on at least two instances we feel it has contributed to a serious accident with pilots who used abrupt power changes the very first time they were airborne and without the benefit of a checkout (see CP #12). What can we learn from this? Where possible, get at

least a back seat check ride from an experienced Viggen pilot, with emphasis on the pitch trim change with abrupt power changes. Particularly at slow speed, and, above all avoid abrupt power changes at low speed until your proficiency allows.

Let me describe a normal take off in my Viggen N27MS. Set half to full reflex (depending on condition, first flight only half) line up on the runway, smoothly apply full throttle with the stick held all the way back. (full aft stick). The airplane will accelerate to 55 - 60 mph and then the canard will begin to fly. As I feel the nose slowly rotate, I smoothly bring the stick forward to pin the nose at the attitude I want for climb. A few seconds later the mains break ground and I get the gear on the way up and run the reflex down to cruise position.

Now, if I maintained the stick all the way back all that would happen, would be a rapid rotation with the steepest climb you could imagine, provided the engine was running at full power, you would climb, but only at 300-500 fpm (depending on gross wt and density altitude). This is not a smart thing to do, even though it can be done in the Viggen, because the abrupt loss of an engine would leave you in a tricky position. Immediate forward stick would probably save the day, but you would have to be sharp!

When we look at the Viggen program so far, obviously we have a problem. This appears to be pilot proficiency and preparedness. Read the owners manual and this article over and over. In all cases where pilots were experienced they had no trouble with the airplane at all. However in two cases now we have seen pilots lose their Viggens on the first lift off in a pitch change with power change. While this has never been a factor for us, it apparently still is a significant factor for a low time, low proficiency pilot. In order to emphasize this, reread the complete writeup on test preparation, pilot preparation and test procedure in CP #12 Page 11. Also, if your Viggen is ready to fly, come to Mojave to take advantage of our offer to allow you to gain some proficiency in N27MS before you begin your testing.

VIGGEN PLANS CHANGES
Owners Manual additions.
Placards

CAUTION! Trim changes with power-forward stick required when power is reduced. (CP #13 page 9).

Minimum and maximum pilot weights must be placarded for the front seat e.g.

Min. Pilot wt	130 lbs.
Max. Pilot wt	210 lbs.

FLASH - This following section was added just as this newsletter went to press:

VARIEZE SEAT BELTS RECALLED
When Johnny Murphy called with information about the accident in Florida, he reported that the pilot's seat belt had come open on impact. The FAA investigator also checked some other VariEzes in the area and found that with a little amount of manipulation the buckles would pop open. We went out to check our airplanes and "GASP" much to our shock ours also "popped" open, so easily in fact that we grounded our aircraft and will not fly one more flight with that style buckle. The buckle is the series E 8000 made by EON Corp (see tag on nylon strap). This buckle is identified by its "cap-over" design in which the release is activated from either end by the cap. The cap extends over the sides and in the closed position its edges are flush with the bottom of the buckle. (see photo and sketch). The problem is that when the occupant is thrown forward, parts of his body, belt, clothing, objects in pockets etc, can be pressed against these edges of the cap and force them forward. This releases the belt. To demonstrate this to yourself grab the straps of the belt and pull the assembly firmly

into your lap when your body is bent over the buckle. Our original thought was to install a "C"-channel under the buckle base that would provide a shield on the sides so the cap is not forced open in a crash. However, we are not seat belt designers and feel that a solution and replacement is the responsibility of the seat belt manufacturer. (EON). We set up a test demonstration of the problem and presented it to the president of EON Dr. Cross. Dr. Cross agrees that the buckles are defective and in fact, was already working with FAA on a recall due to inadequate tongue engagement. EON has agreed to replace all belts at no charge to the customer. We regret that this problem will result in your aircraft being grounded until replacement, but we must recommend that you immediately remove your seat belt assemblies both sides, (not the shoulder harness straps) and send them to EON for replacement. Do not send them to the VariEze distributor, send direct to

EON Corporation
2425 San Fernando Road,
Los Angeles, Ca 90065

Your replacement will be either a previous-design buckle without cap edges or an improved cap-over buckle with side shields. **PHOTO AND SKETCH OMITTED**

CP22, Page 11

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE. The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $3500 (less engine) in about 1200 man-hours or from prefab parts and materials, costing approximately $5000 in about 800 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect, and repair. The VariEze uses the small four cylinder Continental. The Lycoming 0-235 without starter or alternator can also be used. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 22 gallons of fuel. Frontseat passengers up to 6'4" and 220 lb and backseat passengers up to 6'2" and 220 lb. can be accommodated plus a modest amount of baggage in a suitcase. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy

alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM. The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/ components, manufacturing methods testing, and many other.

THE HOMEBUILDER SUPPORT. The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound 11" x 17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, C85, C90, 0-200
SECTION IIC - Lycoming 0-235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/ color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh 72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA SAE, AOPA, AND AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the

Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION.
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.

AIRCRAFT SPRUCE & SPECIALTY CO. 201 W. Truslow Box 424, Fullerton, Ca 92632 (714) 870-7551

MONNETT EXPERIMENTAL AIRCRAFT INC., 955 Grace St Elgin, Ill 60120 (312) 741-2223
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48707
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS 4102 Twining, Riverside, Ca 92509
VariViggen welded nose and main landing gear. 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, Co 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8" x 10" glossy

photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air Mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook i including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues starting with CP#19 are mandatory for those with VariViggen under construction. Identifies new material sources as they become known. Published quarterly. Price - $6.75 per year first class mail. $8.75 per year air mail overseas. Back issues, $1.50 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the part several years. It covers the entire airplane, including the engine installation fuel system, and not only covers the original standard wing in both aluminum and foam an fiberglass composite, but it also includes the composite S.P. wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65 cu inch size. 555-sq wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines) Price - $475 first class mail, $5.50 air mail overseas.

THE CANARD PUSHER No 23 JAN 80

Published quarterly (Jan, Apr, Jly, Oct) by
RUTAN AIRCRAFT FACTORY
Bldg 13, Airport,
Mojave, Ca 93501
(805) 824-2645

U.S. & Canadian subscriptions	$6.75
Overseas (Airmail)	$8.75
Back Issues	$1.50

Note! Price increase for the Canard Pusher Newsletter. This is due to the higher costs of the paper, printing, and builder support. This is our first increase since CP#1 in 1974.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 23. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 23. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 23. If you are building a VariEze from the 2nd Edition plans, you must have newsletters 16 through 23.

A current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 Monday through Saturday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

RAF ACTIVITY since the October '79 newsletter has involved:

(1) Final modifications on the Long-EZ.
(2) Completion of Long-EZ flight tests
(3) Development of new equipment and production method for manufacturing Long-EZ/VariEze landing gear.
(4) Manufacture of new tooling for Long-EZ VariEze landing gear, cowling and other prefab fiberglass parts.
(5) Setting a new worlds distance record with the Long-EZ.
(6) Preparation of drawings for the Long-EZ
(7) Production of Long-EZ/VariEze nose and main landing gear struts.

NEW VARIEZE OWNERS MANUAL The second edition of the EZ manual is over two years old. We have just updated it to a third edition. The third edition includes all the newsletter additions since November 1977. We recommend the new manual for all your VariEze flyers unless you have been complete in writing in all additions.

LONG-EZ PLANS The Long-EZ plans have our number one priority now and Burt and Mike are burning the midnight oil to try to get them out as soon as possible. Considering what is left to do - - typing, proofing, layout, and printing, the best guess is not later than the middle of March.

We are taking names for a mailing list for those who are interested in Long-EZ/Plans. We should have a flyer in two/three weeks which will give the price and availability of the plans. If you would like to be notified, send a self addressed stamped envelope. **CARTOON OMITTED**

VARIEZE/LONG-EZ PREFAB MOLDED FIBERGLASS PARTS
Last newsletter you were told that the new fiberglass manufacturer (for cowlings, nosegear box and strut-cover) would be in production by mid December. There has been at least a 6 week delay in this schedule, due to our failure to obtain our tooling from the previous manufacturer. Our dispute concerning transfer of this tooling appeared to be one that would take considerable time, and result in the non-availability of these important prefab molded parts. So, in November we at RAF undertook the job of manufacturing a completely new set of tooling. This allowed us to incorporate some improvements.

(1) The strut cover was deepened to accommodate both the old and the new (deeper) nose gear strut.
(2) Additional size was added to the Continental cowl where some builders have had interference with the top spark plugs.
(3) Additional size was added to the bottom of both the Continental and Lycoming cowls where clearance with exhaust system bends is marginal.
(4) The lower bumps and entire upper mold-lines of the Lycoming cowl were reduced in size and recontoured to reduce aerodynamic drag.
(5) The Lycoming oil-check door depression was made to accommodate a single-contour aluminum door.
(6) The cowl ribs were extended to seal the cooling air leaks at the trailing edge.

The new tooling was completed in early January and we are currently evaluating several bids from fiberglass shops for manufacturing these parts. We are attempting to get these made at as low as possible prices consistent with acceptable quality. We should have the new manufacturer identified, including price and availability schedule, by the time this newsletter reaches you.

FLASH - As this newsletter is going to print the new fiberglass vendor has been identified. The parts will be available through Aircraft Spruce and Wicks Aircraft Supply - see the flyer in this newsletter for addresses. Contact them for price and availability schedule. The new parts are CI - Cowl Inlet, NB - nosewheel box, SC - Strut cover, CLR - left cowl rib, CRR - right cowl rib, CCT - top Continental cowl, CCB -

bottom Continental Cowl, LCT - top Lycoming cowl and LCB - bottom Lycoming cowl. Later, we will add wheel pants and prefab Long-EZ fuel tanks.

CP23, Page 1

LONG-EZ - THE WHOLE STORY

In late 1978 we at RAF were addressing the enormous task of development and certification of the twin engine Defiant. Knowing that once started, that job would preclude further work on homebuilts for some time, we took a look back at the VariEze status to see if it was really what we wanted to market over the next several years. After accessing what was occurring with a large number of EZ projects, we decided to put the Defiant on the shelf for a while and develop an improved EZ that would solve some remaining problems. The EZ, designed around the A-75 Continental, is generally tailheavy when using an 0-200 with alternator. Also, a large number of builders were being forced into using the 0-235 Lycoming engine because of the high price and scarcity of the Continentals. Even with no engine accessories, their EZ is tail heavy and overweight. They desire electrical systems and need a greater useful load.

We decided to design a new aircraft around the Lycoming 0-235 with starter and alternator. It would have unusually long range, thus the name "Long-EZ". It would have good forward visibility on landing and a lower approach and landing speed than the VariEze, making it more suitable for the low-proficiency pilot and shorter airfields. The original configuration of the Long-EZ used VariEze wings placed out on a centersection spar that was 4 ft longer than a VariEze. The wings were swept more than a VariEze to support the heavier engine. It had "Rhino" rudder on the nose and no control surfaces on the winglets. That aircraft 79RA, was built in four months in the spring of 79 and made its first flight on June 12 '79. It did not fly well. Directional stability was weak. Dihedral effect was excessive. Adverse yaw was high. Roll rate was sluggish. Early airflow separation on the wing caused pitch instability at low speeds. The stall speed was too high.

During the next five weeks, N79RA made 51 flights, testing the effects of over 30 different modifications. Modifications included many configurations of wing leading-edge cuffs, wing fences and vortex generators. The winglet "cant" angle was changed. The ailerons were rigged to various neutral positions. Some of the changes resulted in improvements in pitch stability and lateral-directional flying qualities.

However, we were unable to improve the stall speed, landing attitude and roll rate to a satisfactory level. By August we were convinced that to get the Long-EZ we really wanted, we would have to build an entire new aft wing. The new aft wing, first flown in October '79, had the following improvements:

(1) Less sweep
(2) More area
(3) A new Eppler airfoil similar to that on the Defiant.
(4) Longer ailerons.

(5) Improved winglet juncture to eliminate airflow separation at wingtip.
(6) Overlap-type wing attachment to centersection spar, allowing incidence adjustment and eliminating the expensive fittings.

The new wing performed excellently in test. Approach and stall speeds were lowered. The lower approach and landing attitudes allowed "full stall" landings with good runway visibility. Roll rate was superb. Directional stability was still weak and rudder power at the new lower landing speeds was inadequate. We then built new, larger winglets with rudders and removed the "Rhino" rudder from the nose. That configuration completed flight tests in December '79 with very excellent results in every respect.

It has been shown to be resistant to departure during every conceivable stall entry including tailslides. Its stability is firm even at max aft cg (obtained with a 120 lb pilot with starter, alternator, vacuum pump installed on the 0-235 Lycoming). Even though it has a wing area 41% greater than the VariEze and a 26% greater gross weight, it cruises at 184 mph at 75% - only 10 mph slower than the VariEze.

Designing an aircraft for long range also results in excellent high altitude performance. Even though the Long-EZ has a fixed pitch prop and no turbo charger, it can climb to 18,000 feet in less than 20 minutes and cruise 155 mph true at 23,000 feet at light weights. Maximum ceiling is over 27,000 feet. Its long range and up to 80 mpg per seat economy are more than welcome with todays fuel price and availability.

The Long-EZ is now the recommended airplane for the 0-200 Continental and 0-235 Lycoming engines. Complete electrical systems, including starter and night lighting will be approved. The fuel system and trim system are different from the VariEze. Its 142" span canard and elevators are identical to the VariEze. We will be recommending the VariEze only for the 75 and 85 horsepower engines and of course, still without electrical systems. We at RAF are currently preparing Long-EZ drawings for release to homebuilder by early March. Distribution of materials will be through the same suppliers as for the VariEze. Most of the prefab parts are common. The new wing attachment will not be available for retrofit on a standard VariEze.

Long-EZ flight test data will be published in future C.P. newsletters where room permits. The following table lists specifications and measured preformation of both types. The first column is the VW-powered prototype, a smaller airplane built in 1975 but never marketed.

SPECIFICATIONS/PERFORMANCE OF RUTAN PROTOTYPES

	Prototype N7EZ	VariEze N4EZ	Long-EZ N79RA
Engine	62' hp VW	100hp Cont	108hp Lyc.
Span Ft.	21	22.2	26.3
Total Wing Area Square Ft	59	66.6	94.1
Gross Weight lb.	880	1050	1325
Empty Weight lb	399 bare	585	750 with electric

Useful Load lb.	481	465	575
Weight - solo with 1 hr fuel	598	796	961
Normal fuel capacity gal.	14	28	52
Cabin Length in	95	100	100
Cabin Width in.	21.5	22.2	24.2
Performance at Solo Weight			
Takeoff Distance ft.	660	650	550
S.L. Climb fpm	1680	1900	1750
Max Cruise Speed mph.	175	196	186
Demonstrated Ceiling ft.	N.A.	25,300	26,900
Calibrated Stall speed mph.	64	60	57
Landing Speed mph.	73	69	59
Landing Distance.	N.A.	800	450
Performance at Gross Weight			
Take off Distance ft.	N.A.	860	830

Landing Speed mph	84	74	68
Landing Distance. ft.	N.A.	1000	680

NEW FIRST FLIGHTS The following is a list of those EZs that have flown since C.P.#22. If you know of someone who should be on this list, contact us so they are included should an emergency safety advisory be necessary. If you have an EZ flying and did not get a Christmas card from RAF, contact us, giving name, address, N-Number and date of first flight.

Name	City	State
David Richter	Roselle,	NJ
Rick Himrich	San Antonio	TX
Charlie Richey	Los Cruses	Nm
John Pascarella	Milwaukee	Wi
John Koskan	Wichita,	Ks
Kev Robey	Australia	
Ray Cole	Memphis,	Tn
John Jackson	Jackson	Ms
Steve Darlington	Anderson	In
Bill Keeher	Australia	
Bill Rice	Eureka	Ca
Don Owens	Bedford	Tx

LONG-EZ BREAKS WORLD DISTANCE RECORD
At 7:27 a.m. December 15, 1979 Dick Rutan took off from the Mojave, California Airport in the new Long-EZ prototype in an attempt to break a distance record held by a Czechoslovakian since 1959. The record is distance in a closed course for piston-engine aircraft weighing between 500 and 1000 kilograms (1102 to 2204 lb). The old record was held by

Jiri Kunc who flew 2955.39 miles in a L-40 Metsa Sokal aircraft in August 1959.

When Dick landed at 5:01 p.m. the next day he had covered a distance of about 4900 statute miles, 4800.28 of it credited for the new world's distance record, pending FAI approval. The credited distance is equivalent to a straight line flight from Seattle to London, or from Hawaii to Washington D.C.

Dick's 0-235 Lycoming-powered Long-EZ was modified to carry extra fuel in two wing tanks and a 74 gallon back-seat tank. Takeoff fuel was 143.6 gallons, loading the Long-EZ 600 pounds over its normal 1300 pound gross weight. Initial rate of climb was over 600 ft per minute allowing Dick to promptly climb the heavily-laden Long-EZ to his cruise altitude of 11000 feet. His course took him 15 complete laps between Mojave Airport and the Bishop, California Airport. The entire flight was blessed with perfect weather, cloudless visibility, smooth air, and less than 5 knots average wind at cruise altitude. However, the flight included over 14 hours of darkness over a sparsely populated area requiring extra demands on the pilot for attitude orientation and navigation. The aircraft did not have an autopilot, directional gyro nor attitude indicator.

The solo flight lasted 33 hours, 34 minutes. The average speed for the flight was 145.7 mph. The average fuel flow was 4.17 gallons per hour giving a mileage of 35 miles per gallon (The Long-EZ can attain over 40 miles per gallon at its normal gross weights). Dick landed with 3.75 gallons of fuel on board - enough for an additional 150 miles, but not enough for another lap to Bishop and return.

The 108 horsepower Lycoming engine performed flawlessly despite its 1500-hour-since-overhaul condition. It burned 2.3 quarts of oil during the flight.

Note that, at 1900 lb (300 lb under the allowed maximum for C1B). The range to dry tanks was over 5000 miles. Future attempts, ie, straight line distance, can be flown at 1000 kg take off weight (2205 lb) and achieve over 6500 miles range!

Dick reported the cockpit was extremely comfortable, the only discomfort being suppressing the urge to sleep. The good speed stability allowed extensive cruising without need to monitor airspeed or altitude.

VARIEZE/LONG-EZ LANDING GEAR As noted in the last newsletter, we were required to locate a new manufacturer for the special S-glass main and nose struts for the EZ airplanes. The search for a manufacturer was difficult - the normal fiberglass production shops do not have structural roving experience and do not have the necessary ovens, instrumentation and impregnation machines needed for this work. The shops that do have the equipment and engineering capability to produce these parts are those who only make expensive aircraft components and they have bid excessive prices on these items, to cover the development costs. We were faced with either no landing gear, or a price increase.

We felt that the price of the gear, having been raised 250% since 1976, was already excessive. In early November we decided to tackle the job

ourselves - the only alternative available to provide a reasonable gear for the builders. We knew this job would result in delays in plans preparation for Long-EZ but it really was our only alternative. Within six weeks we did the following: produced patterns and tooling for the new strengthened nose and main gear, developed a new production method, built a convection oven and filament winding machine, setup a quality control process, tested a new epoxy system, and began production of the new parts.

Our new method, which winds roving and tapers it for accurate mold filling, requires less man-hours and results in more uniformity than the previous process. Thus, we are able to sell the parts for only 70% of the previous price per pound.

The new nose gear strut has a deeper cross-section, increasing its strength 20%, yet allowing use of the same NG3, NG4, NG6 and NG15A parts. A gap will exist between NG15A and the forward plate. (ditto for NG6). The new nose gear is also longer, for the Long-EZ - VariEze builders will saw it to length.

The NG-1L strut; being thicker, results in interference at the rod-end when installing NG4 and NG3. We have specified a lengthened NG4, but it will be some time before these are available. In the mean time you should trim NG3 and the strut as shown to clear the rod end. **SKETCH OMITTED**

The new main gear is 65% stronger than the old VariEze gear and should not be susceptible to the long-term creep (spreading and loss of camber) experienced on some of the heavier VariEzes. The new gear is 3 inches longer on each end to raise the prop clearance on the Long-EZ. VariEze builders using the new gear will saw off the 3 inches. The old main gear weighed 16 lb. The new one weighs 21 lb. While we regret any increase in empty weight the experience has shown that many VariEze are being operated heavier than expected and need the extra beef in the gear.

We have completed Chapter 18 of the Long-EZ plans - 4 pages plus a new A5 drawing, that details the installation of the new main gear-to-fuselage attachment. This is a new, wider-stance arrangement that mounts a permanent steel tube on the strut and provides accurate gear installation using one large through-bolt per side. Since several VariEzes have experienced attachment failure due to gear vibration and rough terrain, we have incorporated a considerable amount of extra beef in the new attachment, making it more than twice as strong as the present design. Since many have expressed the desire to install the Long-EZ gear or the Long-EZ gear attachment configuration in their VariEzes, we have printed the Long-EZ Chapter 18 separately and have added an extra page detailing how to install it in a VariEze. This package, called "VariEze Installation -- Long-EZ gear" will be included in VariEze plans, sold after 1st February 1980. If you want this package to retrofit or incorporate in your VariEze currently under construction you can order it from RAF. Price is $7.50, availability is immediate.

Prices - RAF manufactured Landing Gear.
21 lb. Main Gear part # MG1-L - $277.95
2.6 lb Nose Gear part # NG1-L $ 49.75

Prices include packaging. Nose gears can be shipped UPS. Main gears must be shipped via Greyhound bus. Shipments will be sent freight-collect. Or, better yet, pick them up here at RAF. We currently have a 4-week backlog, but expect to catch up to an on-the-shelf basis by mid-March.

CHECKOUTS/FIRST FLIGHT ASSISTANCE

We also get a lot of requests for check outs and rides here at RAF. Although we do this occasionally, it's not within our capability and insurance coverage to do so as a matter of policy. We do recommend you find a local VariEze builder/flyer and have him help you. Generally, an experienced EZ pilot will agree to do your first flight, or at least the first runway flights. This is a very good idea since he knows exactly how your aircraft should fly.

B.B. Williams of 9503 E. 63rd, Suite 110 Raytown, Mo. 64133 has offered to provide a VariEze check to any one about ready to fly. If any others are willing to do this, contact RAF and we will list you in the next CP. For you VariViggen builders, Mike Melvill here at RAF will provide a Viggen check out for those Viggen builders who have their airplanes completed and ready to fly, provided their pilot experience is current. We recommend each of you take advantage of this if at all possible.

VARIEZE CHECK OUTS/FIRST FLIGHTS

In the past we have done considerable preaching about initial flight testing and pilot checkout. We talk about understanding the VariEze differences, being proficient, being current in a number of different aircraft. All these requirements/procedures are necessary and should be followed to the letter to give your "galactic wonder" every chance of surviving its initial steps toward the stratosphere. By this, we have given some the impression the VariEze is a real squirrel to fly. Not true, the great majority of first-time EZ pilots report no problems and surprise at how easy it is to fly. The reason four our preaching is that the majority of problems or accidents have occurred during the early stages of pilot checkout in cases where basic proficiency is low. (reference Canard Pusher #11 through 23).

The following quotes represent an average cross-section of comments we receive about first flights. Experience levels range from student pilot to many-thousand hour military pilots. Student pilot? Yes, Bruce Evans visited us recently on his first solo cross country trip - flying his EZ! Although Bruce has sailplane experience, the EZ was his first powered solo!

Stuart Kingman - "After three years of blood, sweat, and tears I had my own airplane! I taxi tested for two or three days just to get the feel of the airplane, and also because I was scared, and rightfully so after reading of all those experienced pilots getting killed in their EZs! All of my experience rested on 150 hours in a Cessna 150 and one hour in a Grumman TR-2. After the taxi tests, my Dad took out a $10,000 life insurance policy for me, and I lifted N222SK off the pavement and around the pattern! The feeling I had during those few moments were

completely void of any fear - it was the most fun I had ever had! The plane flew as if it had been flying for years. Absolutely no problems whatsoever. What surprised me even more was the landing. I had never flown an airplane with a stick, much less a side stick! That first landing was the smoothest landing I've ever made. Every other landing since then has also been smooth too. N222SK cruises at a true airspeed of 180 mph at 6000 ft and 75% throttle. The engine is a Continental C-90-12F turning a Bruce Tifft prop. Empty weight is 597 lb. I am extremely pleased with the airplane. I have never flown a plane even similar to it. Like I've said many times before, it flies like a airplane should". Stuart is 18 yr old.

Bob Woodall - "Just a quick note to say that I flew N301RW, on July 4. Should have written before - but have been very busy getting in the 25 hours and fixing minor items. Had the 25 hour flight test program completed 16 July. No major problems. She trims easily - very solid at cruise - starts to roll back and forth undamped at 60 mph indicated but no problem to control".

Dan Hogan - "Add another EZ to the list! N5846 made its first flight with Bob Ohletsz's EZ flying chase. Ten hours logged so far - no problems. Thanks for an outstanding design. Quite a change after flying an Ercoupe for 8 years. P.S. There are seven EZs now at Chino Airport".

Lee Roan - "Made first flight on October 21 - something I had not planned to do that day as I had not flown much in the last 5 or 6 months and had not yet had the planned Yankee checkout. I made a high speed taxi, got to 70 mph with nose wheel off then was flying. Pulled throttle back but floated past the half way mark still floating. Decided it was time to fly. I took off and flew around the field and came in too fast the first time so I went around and made a good landing the next time. The plane flies good and I have no problems with it".

Jack Day - "Bill Rogers flew my first flight - first EZ he had flown with cuffs. Says low speed stability is fantastic. Needs more pitch trim".

Norm Ross - "The VariEze is a pleasure to fly".

Dr. James Wright - "My VariEze was easy to fly from the first, even on that first flight after getting over making a fool of myself in a way I would have thought impossible (took off without latching canopy - safety catch caught it). If you fly the aircraft it is a dandy little ship with no real problems at all, that I can see. It has been flown by three other pilots - all report same (two are TWA instructors). I'm pleased with and proud of N26JW - Thank you for a good design and fine support program. When an EZ pilot goes into a new airport he is, indeed a celebrity".

Dan Lee - "After flying experience I can say that my original faith in Burt's design has been justified. It's a remarkable homebuilt".

Jennings Chestnut - "It flew well, no heavy wings etc. I have to adjust pitch spring tension, but outside of that its ready to go. I am real proud of the plane".

Don Youngs - First flight scared him - pitched up and down and did not seem to climb. Made first flight with long canard, narrow elevators and turbulent air. Made both modifications and now reports" "absolutely perfect. Requires a tad of rudder trim and that's all. Very happy with it".

Roger Klemm - "First flight was GREAT! I personally think you have overrated the EZ's "different" handling characteristics. The docile nature of the first flight was wonderful and that was due to all taxi testing and runway flying I did".

J. Steechen - "I'm sure you are tired of excited first time fliers but it did fly great, once I got used to the trim. Thank you for the outstanding builder support".

Jeff Danes - "First flight per the book. Instructions were perfect".

James Langley - "Accelerated to 80 mph, reduced power & lifted off. Everything seemed good so reduced to idle and it settled back to the runway. No problems. Back on the active, repeated the first but brought power back up after lift off. I was off and climbing at 100 mph - after several trips around the pattern approach was made at 100 mph, near approach end power to idle settled on the runway at 80. Wow! what a thrill it is!".

Bob Hudgins - "Straightened out the weight and balance and now it flies and handles great. I really love the way it handles even in gusty and crosswinds I've had no problems" (Bob initially damaged his EZ trying to fly it with cg too far aft).

Tom Bradford - "Your test preparations and procedures were followed and everything worked beautifully. Thanks for 2 years building fun and fantastic very easy VariEze flying".

Rich Clark - "Lift off surprised me. Continuing acceleration with the stick slightly back is a lot different from stabilizing speed with the nose held down. - - - I tried mentally to freeze my hand and succeeded in a series of damped pitch oscillations during initial climb. Roll/yaw ok. I let out a Texas yell, wiggled the wings for the congregation and settled down to trim out. Descent and approach were smooth. Love those ailerons. Over the numbers at 80 knots, overflared up to 20 ft, and another series of pitch oscillations. Eventually E-Z-GO got tired of the comedy and sank to the runway. The solid rumbling of gear on runway and straight rollout were reassuring. Why could I not drive it on? Main factors were pitch sensitivity and Cessna training. Also, confusion with left hand throttle where up is go and down is slow - - Later - - feelin' at home expanding the envelope. Sure enough, won't stall, just nods. Heavy back pressure at low speeds. Easy to locate traffic up here in the bubble. High on final, I ease back to 70 knots to below glide slope. Ease power on to hold it. Good flare and soft rumble and I'm at jogging speed". "Had a lot of confidence before I had flown it, now I have much more".

Steve Darlington - "I can't put into words how much fun it is to fly an aircraft that I built myself. I always get so excited before and after each flight that I usually forget all the flying data. (Now I write it down!). The VariEZE is extremely eze to fly and has very normal flying characteristics being a little more sensitive in pitch than in roll. Ailerons are not as effective as expected but with a little rudder they come alive. The stalls seem to be non-existent at the present time. At full aft stick 1500rpm 55 mph indicated she's still flying with only very small buffeting and all controls still effective. I have had it up to 178 mph indicated at 7000 ft full bore, 2800rpm (195 mph true). A little rpm goes a long ways in the airplane. My EZ is VariEze to land especially with its built-in attitude indicator. (nose canard). If you can't see the runway the nose is too high. Holding the nose off after touch down really slows her down and eliminates heavy braking. Touch and go's are fun since the nose gear never touches the runway.

Gion Bezzola (Swiss Airforce Instructor) - "After putting the plane together and carrying out a comprehensive pre-flight check, according to the American Handbook, I did two taxi tests with the nose up, and another with about 30% power to test the elevators and to get used to them. The nose allowed itself to be lifted from the ground at about 50 mph, and to be held there. The VariEze began to dance about on it's toes as if she couldn't wait to get into the air. I wished to remain captain in charge, so we stayed on the ground a while longer to test the steering. The direction of flight had to be retained with the brakes up to about 30 mph, and above that, the rudder was sufficient. I had to remember to bring my feet back when I wasn't using them, otherwise I would have inadvertently used the brakes. The acceleration was very good. We were very excited before the first lift-off, but this was carried out with no cause for alarm. The wings were flat, the stick was exactly in the neutral position. I got used to the lateral position of the stick very quick and then the Eze was flying, one meter above the ground down the runway. I held the speed at about 80 mph. I decelerated by throttling down slowly, lowered the plane and landed like a feather. The steering felt finely balanced and the brakes were adequate. The first part of the test program, awaited with bated breath, was completed. After four more short flights at a height of 1-2 metres, the inspectors from the Air Ministry arrived and then I was ready for the first big flight of HB-YBG.

The five short flights, the taxi tests, the performance of the engine and the faultless work that the builder had done, gave me a lot of confidence in the machine. We worked out that the center of gravity lay in the allowed area when I was wearing a parachute. The motor was running quietly, and so I asked for starting permission from the Tower. That moment was here again - the first big flight in a new plane, a fantastic exciting moment. I had already experienced such a moment in 1977 when I test flew my own construction the Lutibus, HB-YAY, and now I was looking forward to it again, even though my mind was full of concentration. I opened the throttle, lifted the nose at 50 mph, at 70 mph I lifted the Eze from the runway and held the resulting angle of climb. The angle of climb came as no great surprise to me - I, as a jet-fighter pilot, am already used to such a steep angle of climb! But the fact that this was a home-built machine, powered by only 90 hp, that was a fantastic surprise.

We, the Eze and I, had hardly started, and already I was crazy about her. The steering reacted marvelously, and I trimmed it out with short blips on the electric trim switches. I had to keep watching out that I didn't exceed the permitted maximum speed for a wheel-out flight, because the plane kept wanting to go faster. The Eze was a real little thorough bred! The air-brake worked very well when it was out, and showed this by slightly noticeable buffeting. I realized something pretty quickly: this was probably the most phenomenal plane that I had flown, and I had flown forty different types, Mirage and Hunter included!

After about twenty minutes, I carried out a simulated touch and go, and could judge my imagined landing point very well, a fact that was later supported by the actual landing. On final, at about 90 mph, then over the beginning of the runway with about 80 mph on the clock, the Eze was landed with enough pilot visibility. I landed the Eze and held the nose up in order to brake aerodynamically. Rolling down the long runway gave me time to savor the thrill of the that first flight. I was also pleased for the builder of HB-YBG, who had, through his extremely clean work, given me one of the best flying experiences of my life.

The loud 'hellos' from the spectators who had gathered in the meantime, the happy smile of the builder Rudi Kurth, the congratulations from friends and from the officials of the Air Ministry, was payment enough for the preparation made for this flight, that was threatened at no time by an uncalculated risk. The knowledge that the VariEze constructor, Burt Rutan, knew exactly what he was recommending to future Eze pilots through the handbook, proved to me that a very conscientious pilot was the spiritual father of brand new type of plane. This knowledge grew stronger as the days past, especially when I took the Eze through the stall test, and through the largest part of the tests. How many crashed planes and their pilots could have been saved had this type of plane been designed earlier, because the behaviour of the Eze in extreme conditions is simply fantastic. That a plane can still fly controlled turns when it is stalled, and climbs with full throttle, without the slightest danger of a spin is a wonderful performance of modern aerodynamics.

The manufacturers of conventional planes will have to think again if they wish to equal this type of safe flying. The influence which the VariEze will have on general aviation cannot yet be judged, but I have the feeling that it will be a great influence. After the first flights, I was sure that Rutan had not promised too much. The plane which Rudi Kurth had built was exactly according to the specifications which could be found in the handbook".

Steve Stuff - "First landing like all since then, was very easy, due no doubt to the ground-effect flights. Quite maneuverable, very safe and loads of fun".

LBF RACE 1980 Just a reminder that we are still active in organizing the VariEze class within the LBF race this year at Oshkosh and are expecting a large VariEze turnout. (see C.P. #22 page 1). We are working with the sponsors for the prize money. It will be worth the effort so start planning now. Final details in C.P. #24. See C.P.

#22 and December '78 Sport Aviation for rules. Also, we have decided to allow Long-EZs to compete with VariEzes.

If you as a company or individual would like to help promote this efficiency race by providing a prize/cash for the winners, please contact us before mid March.

CP23, Page 5

SAFE-T-POXY WORKING TEMPERATURE Builder feedback has indicated some difficulty using the Safe-T-Poxy in cold climates. Typical situations are where most EZs are built in garages that are difficult to heat in the winter. Problems are where the builder will heat up the room/garage (air only) and go directly to work but the epoxy, glass, parts, tools etc are still cold-soaked. In use, cold epoxy wets slow and greatly extends the time to wet the cloth properly. The Safe-T-Poxy has a higher viscosity than the previous resins, thus requiring a higher working temperature to use, especially on the larger lay ups. The high viscosity was selected for the Safe-T-Poxy to eliminate the tendency of the previous material to bleed-out (inducing air in the lay up during cure). If you are building in a cold garage in the winter you can still use the new Safe-T-Poxy if you take the following precautions:

(1) Warm the resin and hardener evenly to 85-90 degrees F prior to mixing. Don't try to hurry this. We use a light bulb under the ratio pump 3-4 hours prior to use, or keep your resin jugs in a cabinet with a light bulb inside.

(2) It's important to have everything thoroughly warm prior to starting to work. This also cannot be rushed. It takes time to get the parts (wings, foam blocks, etc) up to a stable temperature through out. If you are starting from a very cold garage the warming process could take 4 hours or more. Don't think just because the air is warm that all the material is warm.

(3) Use an electric hair dryer to warm the area as you work, being careful not to overheat the part or epoxy. When, due to cool temperatures, a part is slow to wet out, a few quick passes with a hair dryer will greatly speed the lay up time. Do not use a hair dryer to heat a cup of epoxy. This can give local hot spots and ruin pot life.

What shop temperature is satisfactory? That has a lot to do with the size of the job. Small jobs can be worked to as low as 65 degrees F but the working time will be excessive. It will also be more difficult to remove excess epoxy, resulting in a heavier part. On large lay-ups like the fuselage, wings, etc, where there is a lot of epoxy to drag around, 77 degrees F should be considered the minimum. That's epoxy prewarmed to 85-90 degrees F and all parts, glass, foam, tools, table -- everything up to 77 degrees F for 4 hours then go to work. Those temperatures are minimums - add 5 to 10 degrees F and your working time will be greatly reduced and parts built lighter. Optimum working temperature range for the current Safe-T-Poxy is 85-95 degrees F. We realize that this is higher than desired, thus we are now working with the formulator, testing improvements. These will be incorporated -

however, by the time the pipeline is filled the cold season will be over.

Safe-T-Poxy is sold in 1 1/2 gallon kits. The price is the same per gallon as the previous resin.

POSSIBLE STROMBERG CARB PROBLEMS Ray Cole from Memphis, Tn. reported to us that he had two engine failures on his first two flights just after take off and has attributed the problem to the original Stromberg carburetor on his C-85. Both forced landings were without damage, which is extremely lucky considering they involved turning back to the airport from only 200 ft altitude! After extensive trouble shooting he determined the climb angle resulted in an uncovered jet in the carb, although this could not be simulated on the ground. He replaced the Stromberg with a Marvel Schebler carb and has had no problem. We here at RAF have no experience with the Stromberg carb and thus could not offer any solution. If anyone out there has had any experience with this carb and could enlighten us please contact us and Ray Cole at 4948 Clear Brook Cove, Memphis, Tn 38118

RESIN/HARDENER STORAGE
(1) Never keep your resin/hardener in a cold place. Even for long term storage. It should be stored at room temperature. If you see your resin start to crystallize and settle out, it's important that it be returned to its normal state as soon as possible even if you don't plan on using it right away.

To return crystallized or separated resin to its normal state put the jugs of resin in hot water 160 - 190 degrees F until the resin clears. Be patient this could take several hours. Occasional mild agitation/shaking will accelerate the process. Leaving the resin hot for 3-5 hours after it clears will reduce its susceptibility to recrystallize. If, after 5 hours at 160-190 degrees F your resin is not clear, return it to the distributor.

VARIEZE SEAT BELT RECALL UPDATE
Reference CP 22 page 11 EON 8000 seat belt buckle recall. We have learned that some of the recalled buckles are being replaced with an improved version of the same 'cap over' design. We found EON is doing this because they had nothing else to replace them with at this time. The improved design has the side edges of the cap trimmed up higher, rather than extending down to flush with the bottom and has the words "lift to open" on the cap. Our tests of the improved E-8000 show that it does not pop open as easily as the previous one. However, if it is placed on the side of the lap over the leg and the body is thrown forward, it can still release - particularly if it snags on your belt or is pressed against an object in a front pants pocket. It is more susceptible to release if it is loosely, rather than tightly, adjusted in your lap. Thus, in our opinion this buckle is not satisfactory.

We just had a meeting with EON and have concluded that the E8000 still requires further modification before it's airworthy. We are very encouraged that EON is willing to redesign and replace the buckle with one that acceptable. However, redesign, tooling, manufacture and delivery will take time. So an immediate solution to those of you that are grounded is not available right now from EON. Those who are

waiting for a buckle replacement should consider an alternate until EON can supply you with an acceptable belt.

Our recommendation to those who have received the "improved" buckle is to conduct your own test - hook the belt to the back of a chair and throw the body forward.

Evaluate for yourself the effects if any protrusion in your lap area coming in contact with the belt side edges - including a pants belt buckle or keys in your pocket. If you agree that there is a problem, write a letter to EON and to FAA describing your concern.

RUDDER TRAVEL In CP #22 Page 8, we issued a Mandatory Grounding bulletin that reduced rudder travel from 3.5" to 2.0". To do this it stated that the cable is cut and shortened. However, due to a missing sentence, it didn't tell which cable to cut. The correct cable that should be shortened is the 3/32" cable that runs from the top hole of VECS 15 bellcrank up to the brake cylinder arm (ref page 16-2 of the plans). Also note that the repeatability of the stop, (rudder out to only 2") depends on the condition of the brake master cylinder. If it leaks or bleeds down the amount of maximum rudder travel will increase. Keep your VariEze brake system in top shape, it's your only means of directional control under about 30 mph speed. What ever you do, don't put any other stop in the system or you will find yourself without brakes.

The rudder deflection bulletin is being repeated in this newsletter with the clarification.

URGENT CONTINENTAL ENGINE DIRECTIVE We had a report of a VariEze Continental 0-200 engine failure due to oil pressure loss. Teardown inspection of the engine found that some of the needle roller bearings out of the starter shaft support found their way into the oil pump, causing considerable mechanical damage. The starter's shaft on some models is supported in the accessory case by a small (.5" dia) needle roller bearing that is pressed into the engine case. When the starter is removed as is the case for VariEze use, this bearing remains in the engine. If the bearing races are worn, the rollers can fall out and then destroy the oil pump or other components. Not all Continental engines have this bearing, some have a pinion pivot. But in any case, each aircraft with a Continental engine that is operating without a starter (normally the starter shaft holds this bearing in place) should immediately be grounded until the following inspection/modification is accomplished.

Pull the starter cover plate on the top of the accessory section and with a mirror and flashlight determine if your engine has this open roller bearing. Be very careful not to drop anything down in the case or you will be faced with an engine removal and teardown to remove it.

The open needle bearing must be removed or "plugged" to prevent the rollers from falling out. We did not have a puller adequate to remove the bearing, so decided to use a plug. The plug is a 1/2" diameter shaft inserted in the hole taking the place of the starter shaft. Refer to the adjacent drawings. Drill and tap a 10-32 thread in the starter cover plate at the location shown. Cut a 1/2" diameter aluminum rod to a length of 3.15". Drill a 3/16" (#10 drill) hole through the center and bolt it to the cover plate with an AN3-34A bolt and AN960-10 washer under the bolt head. Safety it with a MS21042-3 lock nut on the outside of the cover plate. This assembly then inserts into the needle bearing, providing retention of possible loose rollers. **SKETCHES OMITTED**

AEROBATICS We often get asked "is the VariEze aerobatic?" Answer "No". The VariEze was not designed for aerobatics and the flight manual states they are not permitted. Long range cruise efficiency was the design goal rather than any aerobatic capability. Those who want to do aerobatics should consider an airplane specifically designed for aerobatics. Recently Dick and Burt had an opportunity to fly Richard Grunsven's new RV-4 and thoroughly enjoyed it. The RV-4 is an excellent acro aircraft and would recommend it to those who want an aerobatic aircraft.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft Do not fly until the change is been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

VARIEZE PLANS CHANGES

DES Sect III
Page 3 Connect a 6 volt bulb across the two leads to the roll trim servo motor.

MEO Sect V
Page 1 Caution. Never use any (Chemical) paint stripper or solvents on your aircraft fiber glass structure. These materials may not be compatible with the epoxy and damage the basic structure or penetrate the fiber glass and destroy the foam underneath.

MAN-GRD Sect I
Page 19-12-Repeated with clarification from
Sect IV C.P.#22.
Page 28 Rudder Travel - Mandatory change before next flight. Reduce rudder travel from 3.5" to 2.0". This can be done by shortening the vertical cable that runs from the top hole of VECS15 up to the brake arm. Make fine adjustment with the fitting on the top of the master cylinder. The rigging check takes two people - one in the cockpit pushing full rudder pedal

deflection and one measuring at the top of the rudder while applying a mild aft airload (about 3-5 lb) on the rudder trailing edge.

MAN-
GRD Sect IIA Page 1 Sect IV Page 29 Continental engines operating without starter - inspect for open needle bearing. Remove or plug bearing per this newsletter to avoid possible engine damage.

OPT Sect I Page 17-6 You can substitute a HM-6C with a steel insert to 1/4" dia. in place of the RE4M6 rod ends. (suppliers are having trouble getting the RE4M6).

ACCIDENTS In December an Australian VariEze crashed just after take off fatally injuring its owner/pilot. The information we have received to date is sketchy at best, but what appears to have happened is that the pilot made a normal take off to about 20 ft AGL then dove back to the runway hard enough to hit the prop and wheel brake discs. The aircraft then pitched up nearly vertical (70 degrees), rolled inverted and crashed from about 100 foot altitude. This was the pilots first flight in the aircraft.

The aircraft however, had flown 5 hours by a competent pilot, had completed its basic tests including stalls and found to be normal. The accident is still under investigation. If any significant finding is received, we will pass it on.

NEW VDO ENGINE INSTRUMENTS In newsletter 22 we listed a new line of engine instruments we had been testing in the Long-EZ and were very happy with. We also stated the oil pressure indicator could also incorporate a low pressure warning light and run the hour meter only when the engine runs. The following is the wiring-diagram for both the low pressure warning light and the hour meter hook up. Route the 12 volt input through the master switch and protect with a 2 amp breaker. **SKETCH OMITTED**

In newsletter 22 page 5, we listed a set of VDO/CARR instruments that we tested in the Long-EZ. We erroneously listed the cylinder head temp sender Part No. VDO 323-701. This is a sender for a small 14 mm spark plug. Unfortunately VDO does not make a sender for a standard size aircraft spark plug (18mm). However, the Westac CAT sender #712-5W is compatible with the VDO cylinder head temp gauge. Our calibration indicated essentially zero error. Just a reminder to check the calibration of any new gauge prior to use. (see C.P. 19, page 4). Remember these CHT systems are not temperature compensated. They are calibrated to 70 degrees F and read the difference between the sender at the cylinder head and the end of the thermocouple wires coming from the sender. If the air temperature is above 70 degrees F you must add the difference to the gauge reading - if below 70 degrees the difference must be subtracted. So if its 100 degrees F outside, your actual CHT is 30 degrees F more than what's showing on the CHT gauge. Most installations terminate the thermocouple sender wires on the fire

wall and run aircraft wiring up front to the gauge. In this case use the outside air temperature for the correction reference.

LIGHT WEIGHT ALTERNATOR Thanks to a suggestion by Ben Duarte from Richardson Texas. We have adapted a 10 amp Kobota tractor alternator to run on the Long-EZ. The alternator is a small, very rugged, well built unit. Unfortunately extensive machining is required to remove excess material. We have run it over 45 hours with no problems (one flight was 33.5 hours long!) The whole thing is real slick, total weight is under 5 lbs and the hookup/belt drive is very simple. Technically it is not an alternator but a dyno for it has permanent magnets and it's output is not regulated by the field current. The dyno output is constant AC and needs a special rectifier/regulator. If there is enough interest/demand for such a unit we could arrange to have a complete package put together and made available through one of our suppliers. Let us know - should be under $200 complete

OVERSEAS VARIEZE BUILDERS There can be a significant savings in the cost of shipping various items like canopies, cowlings etc overseas if multiple shipments are made (5-10 in one box). Some of the distributors will also discount multiple orders. Attempt to combine orders before contacting the distributor, if possible. If you would like to be the focal point for combining orders in your area send your name and address to RAF, we will print it in a future C.P. newsletter so that other builders in your area can contact you to arrange a multiple shipment.

HOSPITALITY CLUB ACTIVITY The club is planning a get together at Bull Head City Arizona on April 13th and 14th. Rain date is the 19th and 20th April. Camping and motel rooms will be available. For further information about the Bull Head gathering and also the Hospitality Club, contact Don Shupe, 2531 College Lane, La Verne, Ca 91750 (714) 593-1197.

Ed and Joann Hamlin hosted a Hospitality Club New Years Eve party. Seven EZs arrived to join the fun.

FLYING EZE BOOK - "Thank you all 48 who have sent me pictures and wonderful letters, great information. Now please, the other 162 please, I need your pictures etc. to complete the "Flying Eze Book" before we go to Oshkosh this year".

Burt's Mom
Mrs. Irene Rutan,
8526 Calmada,
Whittier, Ca 90605

Mrs. Rutan is the VariEze Hospitality Club historian.

VARIEZE BUILDER HINTS Fuselage - center section spar mating method. You may find it easier to skin the fuselage prior to installing the center section spar. To do this, assemble and glass the fuselage but tack the firewall on for alignment only. Peel ply the skin where the center section spar will be cut out later and around the firewall area. After cure, remove the firewall, cut out the slot for the center section spar and glass on to the fuselage peel ply area with 3 inch wide tapes of 45 degrees BID - 2 plies. Use 2 inch wide tapes lapping

onto the firewall. This allows you to skin the fuselage before building wings and center section spar.

In C.P.#22 we recommended a dual switch that shorts across the roll trim servo motor that keeps it from backing off. Since we published C.P.#22 we have received numerous suggestions on how this could be more easily accomplished. Tom Martin suggested connecting a 6 volt light bulb (available at Radio Shack stores) in parallel with the servo motor (across the two leads to the servo). You "pinball freaks" can mount the bulb where you can see it light up every time you tweak the roll trim! Two other solutions to short the motor are shown below:

Jim Eggelston suggested a single switch that does the job: **SKETCHES OMITTED**

Richard Clark and William Ruben pointed out that the C.P.#22 dual switching is simpler with two single-pole micro switches. Part # 8A1061 micro. **SKETCH OMITTED**

VARIVIGGEN NEWS Not much to report this time, only a few Viggen builders have been in touch. Charles Allen is progressing very well and judging from the photos he sent, he is aiming at a Grand Championship - just beautiful workmanship, Charles. See photos. The French built VariViggen powered by two microturbo jet engines is undergoing flight test and has been featured in several European magazines. Performance figure quoted in "Avimag" are quite impressive: top speed - 248 mph, cruise speed - 198 mph, rate of climb - 1180fpm. Of course this aircraft is a flying test bed for the microturbo engines, and is not a real ideal "homebuilt" due to severe range limitations, range is only about 200/250 miles or 1 hour of flying time!

N27MS now has 400 hours on it and just over 500 landings. This means that the worm gear main gear retract system (now standard in the 2nd Edition Plans) has over 500 cycles under load on it, with absolutely no problems whatsoever. The only problems I have had have been the alternator, which for some reason or another, have failed at a rate of one every 100 hours. My alternator is a Chrysler product, standard equipment on many Piper aircraft, and is a certified aircraft part. All four failures have been different, bearings, diodes, field coil windings failed, etc. Anyway, I have decided to try a different make of alternator, and am in the process of installing a brand new Alcor (Motorola) ?? amp alternator. I intend ducting cold air onto the alternator, even though I tried that with the last Chrysler one, without much success. The Alcor has about three times the warranty so hopefully I will have more luck.

The other thing that has come up is brakes. N27MS never has had very good brakes. They have been adequate but not near as powerful as Burt's N27VV. Both aircraft have Cleveland 500 x 5 wheels, tires and brake calipers. This has puzzled me to the point that some time ago I went in and changed the pedal to master cylinder leverage ratio. This helped some, but did not give the expected results.

Building and flying the Long-EZ which has the same wheels and brakes, I was amazed at the tremendous braking power it has. Even allowing for the difference in gross weights, it was much superior to mine, so I looked little further, and don't know why I did not catch it before. What I had done was to buy a brand new set of 500 x 5 Cleveland wheels and brakes, and then because I was "cheap", I bought Gerdes master cylinders instead of Clevelands because at the time they were about half the price. it turns out that the Gerdes master cylinder piston is .625" in diameter, and the Cleveland is .562" in diameter. This does not seem like much, but makes all the difference in the world. The Gerdes wheels and brake calipers work fine with the Gerdes master cylinders, the piston in the caliper is larger and thus they work well together. However I am not positive but I believe the Gerdes wheel and brake assembly is wider and may not fit up into a Viggen wheel well,

the Clevelands only just barely fit. The moral here of course is to be sure you have compatible brake cylinder/brake caliper combination. The Rosenhaan brake master cylinder is .50" in diameter and is compatible with the Cleveland wheels and brakes, and at a much more affordable price than the Cleveland master cylinders.

Charles Allen's Viggen - note all equipment installed before skinning fuselage. **PHOTOS OMITTED**

Oblique Wing Aircraft in First Flight
National Aeronautics and Space Administration's AD-1 oblique-wing research aircraft flew its first flight Dec. 21 and is expected to begin skewed-wing flight tests around mid-February, following a series of preliminary test flights aimed at gathering base data with the wing in a normal perpendicular position with respect to the fuselage (AW&ST Jan. 7, p. 14). The wing can be pivoted up to 60 deg. from the normal perpendicular position. Propulsion is provided by two Microturbo TSR-18 turbojets of 220 lb. thrust each. NASA is studying the application of the oblique wing concept to future high-speed transport aircraft, where the wing would be pivoted at higher speeds to reduce drag and thereby allow higher speeds and longer range for the same fuel expenditure.

RAF-designed AD-1 skew wing aircraft is now in flight test. Article from Aviation Week.**PHOTO OMITTED**

DC-100 STYLE VARIEZE MARKET SURVEY. Most of us agree it would be nice if we could carry more passengers in our VariEzes. A builder in Western Massachusetts has come up with a kit to modify your VariEze so that it will carry 310 passengers, a pilot, co-pilot, engineer and six Swedish stewardesses. The full kit including three jet engines, plans, materials, 2,500 gals resin shipped to the siding of your choice and

will probably cost $1,310,000. We would consider making the system available as a kit or fully assembled if there is enough interest.

VariEze

TODAY'S HOMEBUILT WITH TOMORROW'S TECHNOLOGY

PHOTO OMITTED

THE AIRPLANE. The VariEze is a small, high-performance homebuilt sportplane. It can be built from raw materials costing approximately $3500 (less engine) in about 1200 man-hours or from prefab parts and materials, costing approximately $5000 in about 800 man-hours (about eight months spare time work). Its structure is a sandwich of high-strength fiberglass, using low-density, rigid foam as core material. The structure is fabricated directly over the shaped core, thus expensive tools and molds are not required. Composite-sandwich structure offers the following advantages over conventional wood or metal: less construction time requiring less skills, improved corrosion resistance, improved contour stability, better surface durability, dramatic reduction in hardware and number of parts, easier to inspect, and repair. The VariEze uses the small four cylinder Continental. The Lycoming 0-235 without starter or alternator can also be used. The airplane has exceptional climb and cruise performance. It can carry two people 700 miles at 185 mph on less than 22 gallons of fuel. Frontseat passengers up to 6'4" and 220 lb and backseat passengers up to 6'2" and 220 lb. can be accommodated plus a modest amount of baggage in a suitcase. The airplane does not have full dual controls, but does have a backseat control stick. Due to its small size (only 67-sq.ft. wing area) it is not the airplane for installing extra equipment for IFR, night flying, etc. It can handle a simple electrical system with a single NAV COM and gyro instrument. These can even be powered with a solar panel, thus eliminating the heavy alternator. The VariEze is recommended for day-VFR operation only. Due to its relatively high landing speed (70 mph) and small tires, it is acceptable only for smooth, hard-surface runways. Its stability and overall flying qualities are superb. Once trimmed, it will hold attitude and level flight "hands-off" even in turbulence. Trim changes due to power, gear retraction, or landing brake are all very small. Its unique aerodynamic design allows it to be flown with full aft-stick, at less than 50 knots, without a stall departure or loss of control, and without altitude loss. The VariEze uses the latest aerodynamic features: NASA winglets, both wings cruise at best L/D, basic arrangement provides stall safety, stiff structure provides accurate contour maintenance, basic system's design eliminates or combines

complex control systems, which saves weight, cost and building time while increasing reliability and lowering maintenance.

THE TEST PROGRAM. The VariEze test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/ components, manufacturing methods testing, and many other.

THE HOMEBUILDER SUPPORT. The manufacturing manual is a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, "The Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire VariEze except engine installation. The manual consists of a 153-page, bound 11" x 17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles instrumentation, electricals, fuel, exhaust and

induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental A65, C85, C90, 0-200
SECTION IIC - Lycoming 0-235 - No accessories.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring/priming/U.V. barrier/ color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft long can be used with appropriate pilot proficiency.

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh 72.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA SAE, AOPA, AND AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43kts) it will still climb 500 fpm roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The prototype received the Omni Aviation safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

EXCELLENT UTILITY
Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. Its unusual design turns routine travel into "fun trips". Gas service and other airport services have been better too! Take it home; it's road-towable with outer panels removed.

UNCOMPLICATED CONSTRUCTION.
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in

fiberglass, ready to install. All machined parts are also available, as well as other prefab parts.

EASY TO FLY
Despite its unique appearance, the VariViggen has no unusual or pilot-demanding flight characteristics. It is easier to handle than conventional aircraft, particularly in gusty crosswind conditions.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.

AIRCRAFT SPRUCE & SPECIALTY CO. 201 W. Truslow Box 424, Fullerton, Ca 92632 (714) 870-7551
VariViggen spruce kit, plywood kit, hardware, all aluminum and fiberglass. Catalog cost $3.

KEN BROCK MFG. 11852 Western Ave., Stanton, Ca 90680. (714) 898-4366.
VariViggen prefabricated components: all machined parts. Catalog costs $2.

THE AIRPLANE FACTORY, 7111-A Brandtvista Ave., Dayton, Ohio 45424. (513) 845-9872
VariViggen plexiglass canopy

BILL CAMPBELL Box 253 Phelan, Ca 92371
VariViggen brackets and fittings.

MONNETT EXPERIMENTAL AIRCRAFT INC., 955 Grace St Elgin, Ill 60120 (312) 741-2223
VariViggen molded fiberglass parts.

GOUGEON BROTHERS, 706 Martin, Bay City, Mi 48707
VariViggen 105/206 epoxy and 403 fibers for wood construction.

GEORGE EVANS 4102 Twining, Riverside, Ca 92509
VariViggen welded nose and main landing gear. 1-1/4" sq. steel tube.

JESSE WRIGHT (VariViggen builder) 7221 S. Colorado Ct. Littleton, Co 80122 (303) 771-5140
VariViggen prefab wood parts. Send 50 cents for list.

VARIVIGGEN TECHNICAL REPORT - Complete tech report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view, stability and performance flight test data, construction cost, description of car-top wind tunnel, 8" x 10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Air Mail overseas.

VARIVIGGEN OWNERS MANUAL - Complete operational handbook i including normal and emergency procedures, loading, operational record keeping. This manual is a must for those close to first flight. Price - $6.00 first class mail, $7.50 Air mail overseas.

"CANARD PUSHER" SUBSCRIPTION - A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements, building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription and back issues

starting with CP#19 are mandatory for those with VariViggen under construction. Identifies new material sources as they become known. Published quarterly. Price - $6.75 per year first class mail. $8.75 per year air mail overseas. Back issues, $1.50 ea.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the part several years. It covers the entire airplane, including the engine installation fuel system, and not only covers the original standard wing in both aluminum and foam an fiberglass composite, but it also includes the composite S.P. wing, ailerons, and rudders. The manual identifies sources for all required materials and all available prefabricated parts and components. Price - $165.00 first class mail, $177.00 Airmail overseas.

VARIVIGGEN R/C MODEL PLANS - Complete construction plans for the 18% - size radio controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65 cu inch size. 555-sq wing area. All balsa or foam/balsa construction. A maneuverable flying model with outstanding roll rate. Also shown are modifications required for a control-line model (70-ft lines, .19 to .45-cu inch engines) Price - $475 first class mail, $5.50 air mail overseas.

Four-place VariEze! Ken Swain and family on arrival at Hospitality Club's Columbia Flyin. The twins ride papoose-style in special pouches. Ken says they now have grown too heavy. **PHOTO OMITTED**

CP23, Page 14

THE CANARD PUSHER NO 24 APR 80

Published quarterly (Jan, Apr, Jly, Oct) by
RUTAN AIRCRAFT FACTORY,
Bldg 13, Mojave Airport,
Mojave, Ca 93501
(805)824-2645

U.S. and Canadian subscriptions	$6.75
Overseas (AIRMAIL)	$8.75
Back Issues	$1.50

Note! Price increase for the Canard Pusher Newsletter. This is due to the higher costs of the paper, printing and builder support. This is our first increase since CP #1 in 1974.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 24. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 24. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 24. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 24. If you are building a Long-EZ from 1st Edition plans you must have newsletter #24.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.
If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

SATURDAY DEMOS RESUMED
In 1975 and 1976 our offices were located remote from our prototype aircraft making it difficult to show them to visitors on an individual basis. Therefore, at that time we had a formal display of the airplanes, including a flight demo each Saturday at noon. After we had our new building on the flight line in 1977, our airplanes were available for public inspection daily, and due to our being gone on occasional weekends, we discontinued the Saturday demos.

Lately, during the last few months, we have had a large number of Saturday visitors, and we have been rolling all the airplanes out for flight demos, including our airshow practice with formation flying etc. These have been well received and thus, we now plan to resume our policy of a scheduled flight demo and composite construction discussion period every Saturday that is not reserved for an out-of-town EAA flyin. We will start the presentation/discussion at 10 am each Saturday with flight demos of our experimental aircraft at approximately noon (weather permitting). This will be done each Saturday except when we will be gone to the following airshows:

26 April 80	Chino, CA	Flyin
24 May 80	Watsonville, CA	Flyin
31 May 80	Lake Isabella, CA	Hospitality Club
2 Aug 80	Oshkosh, Wisc.	EAA Convention
9 Aug 80	Oshkosh, Wisc.	EAA Convention

Bring any of your parts for inspection. We are located near the west end of the flight line at the Mojave Airport about 2 hours drive north of Los Angeles on Highway 14. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

LONG-EZ AT SUN-'n-FUN, by Dick Rutan
I just returned from a very successful two week trip to the 1980 Sun-n'-Fun flyin at Lakeland, Florida, with the Long-EZ. We originally planned to go non-stop from Mojave to Lakeland at a economy cruise speed. However, before departure we modified the wing strake fuel tank into a baggage compartment, reducing the volume of fuel. With only 50 gallons, non-stop it is possible only with a moderate tailwind. Note that with the strake baggage compartment the prototype has about the same fuel volume as the plan-built Long-EZ. With Pilot, 50 gallon fuel and about 100 lbs of baggage the aircraft was operating near its design gross weight of 1325 lbs. Since I could not fly non-stop I wanted to fly at high cruise speed and fly near the maximum range. The first leg was a "short" 756 sm from Mojave to El Paso, Texas. The second leg was 1506 sm from El Paso, Texas non-stop to Lakeland, Florida. That leg took 8.12 hours at an average 185.5 mph ground speed (tailwind averaged 5 mph). I had fuel remaining at Lakeland to go an additional 170 miles. The fuel flow averaged 5.5 gph at 180 mph true. Some of the cruise data collected are listed:

Alt.	Full Throttle	MP	TAS	GPH	MI/GAL	RPM
9500	Yes	19.2"	182	5.65	32.2	2780
11,500	No	18.0"	175	4.80	36.4	2756
13,500	Yes	18.1"	176	4.75	37.05	2740

On my arrival in the Lakeland area I found myself surrounded by VariEzes escorting me in. We did a formation fly-by and landed. The participation by the "gallactic wonders" at Lakeland was excellent - 16 total, by far the most popular homebuilt in attendance. There were 15 VariEzes and one Long-EZ. Some of the VariEze activities included a designers' award for the best EZ, a VariEze race, a daily bull session and an awards banquet. The award for the best EZ went to Steve Darlington from Anderson, Indiana, immaculate N36SD. Congratulations Steve on a job well done.

The race was flown on Friday just before a mild weather front went through. Bringing 3 hours of the only rain we had all week. We wanted to fly the race out of Lakeland and back to finish in front of the crowd but the air traffic was such that this was not feasible. So we ran the race out of an airfield 15 miles east of Lakeland. We set up a triangular course of 46 total miles. I did not want to get involved in complicated timing or handicapping and wanted the first one across the finish line to be the winner. But 9 VariEzes are tough to start all at once so we staggered the start based on engine size. This put the C-90 out front, the O-200 next and the Lycomings last. The whole gaggle got off in less that 40 seconds and they were all really close at the first turn. Some sight to see all those weird birds so close going around the first pylon. Rounding the last pylon before the finish we had Steve Wood with his boat tail NACA air scoop Continental O-200 Eze in the lead, or so we thought, but much to my surprise Ed Rockwell in his C-90 N7ER was turning the pylon a good mile out in front. Steve Woods was gaining, it looked like a horse race finish right to the wire. The rule was that you must fly down the runway and the first one to cross the intersection at midfield was the winner. Since the approach was about 90 degrees to the runway it meant a turn around the numbers then down the runway. Well, unfortunately Ed made this turn a little wide and Steve, an old race pilot, cut him off and finished just 5 seconds ahead to win. Results follow. Note that even though the Long-EZ has 41% more wing area than a VariEze, it was faster than 4 of the VariEzes. The speeds listed are not corrected for the start interval or losses in the turns. For example, based on actual start times, Steve Wood turned 196.3 mph and the Long-EZ turned 185.7 mph. Two of the EZs were running TAS over 200 mph in the straightaways.

SUN-'N-FUN EZ RACE RESULTS

Placing	Aircraft		Pilot	Speed-not corrected for start handicap.
1	VariEze N56EZ	O-200	Steve Wood	186.8 mph
2	VariEze N7ER	C-90	Ed Rockwell	185.8 mph
3	VariEze N2UM	118 Lyc	Lance Uhley	183.5 mph
4	Long-EZ N79RA	108 Lyc	Dick Rutan	180.8 mph
5	VariEze N57EZ	O-200	Byron McKean	180.6 mph
6	VariEze N36SD	O-200	Steve Darlington	171.9 mph
7	VariEze N70VE	O-200	Herb Sanders	170.8 mph
8	VariEze N2286A	O-200	Mule Ferguson	169.7 mph
9	VariEze N301RW	O-200	Bob Woodall	163.6 mph

The demonstration flown by the Long-EZ at airshow time was intended to show its excellent glide ratio, good maneuverability and wide stall margin. To demonstrate this and to dispel the doubts about canard stability and control we worked up a low altitude, simple aerobatic routine. We want to make it clear that the Long-EZ is not designed for aerobatics and, while we don't recommend it for aerobatics, in the hands of a competent aerobatic pilot the basic positive "g" aerobatics can be easily performed. The 4.5 minute routine flown at Lakeland went like this: Take off at minimum speed, enter a steep bank, full aft stick "corkscrew" climb 720 degree turn to about 500 feet then descent to gain speed and do the same thing starting at 120 knots 4 "g" full

aft stick 70 degree bank topping out at 1200 feet, then split "S" to 200 feet at 150 knots for a loop, a roll, then a split "S" reversal for a Cuban "8". Then, another split "S" reversal to attain 180 knots. At 200 feet, show line center, kill the engine and do a loop, a roll, a 180 degree climbing turn back to show line center. Now at 500 feet and at final approach speed, 65 knots do two 360 degree spiral turns landing show line center all dead stick. Impressive ??? You bet - - - - We received numerous letters, calls, and personal comments at the flyin - - - "I had no idea that that could be done etc. etc. - - -". We have even received a formal request to perform at the 1980 World Aerobatic Championships to show the foreign countries what is available here.

During the return from Lakeland, I stopped off to visit some local EAA chapters at Dallas, Austin and Phoenix. Total flight time 52.2 hours, two weeks on the road, used 279.0 gallons of fuel for an average of 5.34 gallons per hour. Much of the flying was spent giving back seat rides and checking out six new pilots in the front seat.

BURT'S TRIP DOWNUNDER
At the invitation of the Sport Aviation enthusiasts of New Zealand and Australia, Burt traveled to those countries in March/April. Purpose of the trip was to conduct composite structure workshops and to discuss composite inspection with homebuilt inspection agencies. The hospitality was great. Burt stayed with ten different EAA families. In addition to some sight seeing, Burt was able to inspect several VariViggen and VariEze projects under construction and fly two VariEzes. At the Latrobe Valley flyin near Melborne there were 4 VariEzes flown in to join the 54 other homebuilts in the Australia National Flyin. Two of them flew more than 2400 miles from Western Australia. Congratulations Noel Bramish, Geoff Danes, Ian Clubb and Bob Keehner on four beautiful EZs. Thanks also to Tony Stinton, Ian Williams and the other EAA'ers who worked so hard to arrange the trip. Some observations of interest to us American homebuilders:

Even though New Zealand only has 3.5 million population, they had 53 homebuilts at their January flyin!! Their activity is high despite tight government control: All materials purchases must be accompanied by a release note. Workshop must be approved before you can start building. Only specific designs may be built. Any modifications must be approved and documented with drawings and engineering. Stage inspection is intensive - even the book ends must be approved! No material substitute is allowed. Test pilot must be approved.

Both Australia and New Zealand Governments provide a composite aircraft construction school to teach methods and inspection. Some of the class projects include building a VariEze, our confidence samples and bookends.

HOSPITALITY CLUB FLYIN at Bullhead City, AZ, by Mike Melvill
With Burt still on a trip to Australia, Dick in the Long-EZ and myself and my Mother in the VariViggen, took off from Mojave and headed east. Perfect weather with unlimited visibility made for a very pleasant flight. Dick occupies himself with fuel flow checks at various power settings and altitudes. We started out on the deck and ended up at 11,000 feet. One hour and thirty minutes later we made a two ship formation flyby at Bullhead, and counted 11 VariEze's on the ramp.

We all crossed the river on the ferry boat and had an early lunch in the casino restaurant. We lost a couple of dollars very quickly, then crossed back to the airport where we spent the rest of the day chatting with all the EZ pilots, potential pilots and general public. Both Dick and I gave short demonstration flybys, later in the day, and Dick treated everyone to most of his "Sun-'n-Fun" aerobatic show.

As it got dark, there were 16 VariEzes, 1 Long-EZ and 1 VariViggen on the field. We all crossed to the casino where we had an excellent buffet dinner for only $4.00. After dinner, Dick showed some breath-taking slides of the Long-EZ doing aerobatics shot from an aft-looking camera, mounted on the nose.

Don Shupe gave out several awards, and Dick awarded a VariEze belt buckle to Gary Hertzler of Tempe, AZ, for having the most outstanding VariEze. A real jewel, powered by a Continental A80. After dinner we checked out the various gambling spots along the Nevada shore of the Colorado river. It was a lot of fun, but could cost you money if you were not careful!

Early next morning 5 VariEzes were out in a dawn patrol flight, while the rest of us were trying to sleep! After a hearty breakfast at the casino, we spent an enjoyable morning looking inside cowlings, and answering questions, and generally having a good time. I must say the feeling of being with a bunch of VariEze pilots, their wives and girlfriends like that, is great.

I took Bruce Evans for a ride in my Viggen, then Dick did his aerobatic show, and we all started heading for home. A total of 18 EZ's 1 Long-EZ and 1 Viggen actually flew in. EZ's came in from as far away as Redding, CA, and Los Cruces, New Mexico.

We did a couple of close formation flyby's then headed back to Mojave. Time enroute 1:20. We really had a great time and vowed to try to get to any future Hospitality Club flyins. Congratulations to the organizers of a really fun flyin, let's do it again, soon.

LAKE ISABELLA HOSPITALITY FLY-IN
The Hospitality Club is planning their next fly-in for May 31st and June 1st. This will be at California's Lake Isabella in the Kern Valley. There are plenty of camping areas, the lake is within walking distance as well as the river. A really beautiful area for a fly-in. For more details call either of the following - Bruce and Bonnie Tifft (805) 649-2721, Don & Bernadette Shupe (714) 593-1197.

HOSPITALITY CLUB PROPOSED TRIP to the Bahamas.
Plans are still very tentative but at this point we are planning to depart California on December 20th, spend one week in transit, and plan to be in the Bahamas from 27th on. We are planning to take 3 weeks. However there are many of you out there with only 2 weeks, and of course you could get over there easily in a couple of days, depending on weather. If anyone would like more information on this trip contact: Bruce and Bonnie Tifft,
8746 Ventura Ave,
Ventura, CA 93001
(805) 649-2721 (evenings)

We hope to have firm plans and dates within the next few weeks so we can proceed with reservations and deposits.

SAFETY MODIFICATIONS by Dick.
During my travels I am dismayed at the number of VariEzes flying that have not accomplished the safety modifications. Check CP #21, pg 4-5, CP #22 pg 8, CP #23 pg 7. Things like rudder travel, Continental O-200 starter bearing plug, 1/4" rod ends, canopy safety latch, EON-8000 seat belt buckle, etc, etc, are extremely important and should be accomplished immediately. Do not procrastinate with safety.

LONG-EZ UPDATE
(See also Long-EZ flyer, "Which one?" and "Sun-'n-Fun" in this issue, and CP #23).
Long-EZ plans are now available!!
The major benefits of the Long-EZ over the VariEze are listed below:

(1) Lower (65 kts) landing approach speed, can touch down at 50 kts with full aft stick.
(2) Better visibility for takeoff, approach and landing.
(3) Higher roll rate, lighter and more responsive ailerons.
(4) Stiffer elevator forces, more solid feel in pitch.
(5) Increased useful load, cabin size and instrument panel space.
(6) More baggage area. Cabin-accessible area in wing strakes.
(7) 60% more range and less runway required.
(8) Better high-altitude performance.
(9) Better maneuverability, yet more docile for low proficiency pilots.
(10) Greater stall margin.
(11) Ability to use 100 to 118 hp engines without nose ballast.
(12) Ability to use lighting, alternator and starter.
(13) Ability to use 500 x 5 tires.
(14) Improved structural materials.
(15) Improved structural methods and easier jigging.
(16) Overlap, incidence - adjustable wing attach (no wing fittings).
(17) Improved trim, electrical, and fuel systems.

The major benefits of the VariEze over the Long-EZ are listed below:

(1) Lower cost - materials are approximately $500 less due to smaller size and cheaper type foam.
(2) Ability to use the A75, A80 and C85 engines.
(3) Easier to trailer (Long-EZ must be tilted to meet the 8 ft width requirement).
(4) Faster to build (Long-EZ requires about 15% more work).

Note that there is only a minor difference in speed. Our Long-EZ outran half the VariEzes in the Sun-'n-Fun race.

The adjacent photos show Johnny Murphy of Cape Canaveral with his Long-EZ. This is the #2 ship, started last year. Johnny's project was built from the plans before they went to the printer, thus he provided assistance in debugging the plans. The Long-EZ plans are layed-out and

detailed very clearly and completely. They are drawn based on our experience providing support for over 2000 VariEze builders. Thus, we expect far fewer changes and building problems than with the VariEze.

The Long-EZ design has taken advantage of the numerous improvements noted based on over 250 EZ first flights. Testing has been more extensive. When the VariEze plans first went to print in 1976 the prototype had 100 hours flying in 4 months and had been flown by about 6 pilots. Long-EZ prototype has over 250 hours flying in 10 months and has been flown by 25 pilots (front seat).

Our original plan of a addendum rather than a new set of plans was foolish, since even the unchanged canard and elevators were redrawn to improve their clarity and to eliminate common builder errors. The Long-EZ plans Section I include finishing instructions and complete electrical system drawings. Section IV is required and IIA or IIC are needed for engine installation. The Long-EZ Section I includes all updates for these Sections. Thus, Long-EZ builders do not need newsletters previous to CP #24.

The fact that the Long-EZ plans are completely new rather than an addendum eliminates the confusion of plans editing. However, some of you have purchased VariEze plans with the intent to build a Long-EZ when the addendum was published. Thus, we are providing a plans trade-in program so those people can get credit toward the Long-EZ plans. If you bought a VariEze Section I from RAF after July 15, 1979 with the intent to build a Long-EZ, contact RAF for terms for trading them for the Long-EZ plans.

We are just now finishing the Long-EZ Owners Manual. It should be printed and available by the end of May.

LBF RACE - OSHKOSH 1980 - We are still active in planning a VariEze/Long-EZ class race in the LBF race this year at Oshkosh. Since a VariEze is not competitive with the best formula racers for the major purse, we have established a class within the race for the fastest VariEze in each of the three categories. We have been successful in getting $1200 so far for prize money and this could double by race time. The race is a timed speed/efficiency contest. You get 18 gallons to go 500 sm and the fastest using no more than 18 gallons wins. You get credit (speed adjustment) for fuel not used under 18 gallons. Use more than 18 gallons and you're disqualified. I just learned from the LBF organizer Nick Jones that he is now giving prize money to more than just the 1st place winner - $500 for 2nd, $250 for 3rd, $150 for 4th and $100 for 5th. We may have some EZs in this money or maybe the $7000 overall purse!! You never can tell what will happen in a race so start planning now.

For rules, see the December 1978 Sport Aviation, C.P. #22 or an upcoming Sport Aviation. You can write to the race director -

Aaron King
1893 Greystone Road,
Atlanta, GA 30318

for an application, race number and official rules. There is a $10 registration fee and you can request your race number at that time. (list 3 choices for race number). Get your applications in now before

the good numbers are taken. You must be registered prior to the July cut off to race. See you on Race Day.

TWO PHOTOS OF JOHNNY MURPHY'S LONG-EZ UNDER CONSTRUCTION OMITTED

FLASH - At the down-under fuel efficiency race held 6 April 1980 in Australia (same rules as LBF), Geoff Danes VariEze easily won over 4 other types. Placing and fuel-corrected speeds are listed below.

1st	VariEze	174.5 mph
2nd	Mustang II	160.2 mph
3rd	Cassett	160.0 mph
4th	Tailwind	154.2 mph
5th	T-18	Disq - used too much fuel

LONG-EZ/VARIEZE MIX
We have had many requests concerning the possibility of converting partially completed and even complete VariEzes into Long-EZs. This may work, and may fly ok. However, since we have not done it ourselves, and have not flight tested it, we can not recommend it, and neither can we provide builder support for those who elect to do it. Anyone who elects to try to do this is entirely on his or her own, and it will be your responsibility to handle all modifications, to foresee any interference problems and to fit parts that may not go together. We would also request that you do not call your airplane a VariEze or Long-EZ. Please call it something else like "Smith Special" etc. Remember, you will be doing exploratory flight tests where all characteristics are in question until you have flown and tested them. We are supporting over 2,000 builders now, and there would not be enough hours in the day for us to be able to work out problems with individual builders of a "hybrid". Please don't ask us, because we will have to say no.

WEIGHT CONTROL - Too many builders are loading their airplanes down with extra equipment and heavy finish jobs. They are going to miss the real thrill of flying their EZ at a light weight, and they will find their useful load disappearing. Here is the trap -- if you address each item as, "Oh, that's only one/half pound, it's a small percent of the empty weight", you will find that the sum of all the extras will add up, and when you weigh your ready-to-fly airplane you will be scratching your head and saying, "where is it all?". Believe me, it happens every time.

We have a strong recommendation for all of you, and that is to delay installation of any equipment not absolutely required for flight, until after you have flown your airplane a few hours. Then, you will have a much better chance of a successful flight test program -- the airplane is easier to fly light and uses less runway. Also, if you make a real bad landing during your transit it will put a lot less stress on your landing gear. Then if you must, load on the equipment, at least you will get to see first-hand the effect it has on performance and runway requirements.

This philosophy also goes for modifications, too. Don't try something new on your unflown new airplane. Build to the plans first, where you know from our experience that it will work. Fly it that way, then try your modifications.

EON E-8000 SEAT BELT UPDATE
In CP #22 we reported the EON E-8000 seat belt was unairworthy and that Dr. Cross, President of EON Corp would. replace the belts with one that was acceptable. Unfortunately Dr. Cross reneged on his commitment. Long delays were reported and the ones he did replace were still the same type (dash 4) and in our opinion still unsatisfactory. We recommended the EON E-8000 be removed from your aircraft and replaced with another approved style. We have been very active with the FAA to the the cap-over buckle recalled. Now, over 5 months since we recalled the buckle and pointed it out to the FAA and EON, Airworthiness Directive dated 4 March 1980 80-05-04 amendment 39-3706 has also recalled them.

PROPS FOR VARIEZE AND LONG-EZ
We have approved and recommended the following prop manufacturers.

Larry Weishaar
1924 No. 6th
Springfield, IL 62702
(217)544-6086
(Homebuilt prop)

Ted's Custom Props
Ted Hendrickson
9917 Airport Way
Snohomish, WA 98290
(206)568-6792

B & T Props,
5746 Ventura Ave.
Ventura, CA 93001
(805)649-2721

Bill Cassidy
4652 Montview Blvd,
Denver, CO 80207
(303)322-3423

Ray Hegy
Marfa, TX 79843
(915)729-4249

Most of our testing has been done using Ted's props, and therefore we tend to compare everyone else's to Ted's. Ted reports that he has finally caught up his VariEze prop production to where he can offer much better delivery than he has been able to over the past year or so. He also reports that, lately he has been supplying steeper pitch props to O-235 Lycoming powered VariEzes in the form of a 58 x 74 and in some cases 58 x 76 prop. A couple of builders using these props have reported good results. We are presently using a Ted's 58 x 72 on the Long-EZ.

Any potential prop makers who would like us to recommend their props on either the VariEze or the Long-EZ or both, should send us a representative prop, which we will test on our prototypes, and if it comes up to our standards, we will keep the prop for further testing and approve and recommend it in the Canard Pusher. If it does not meet our standards it will returned freight collect.

PREFAB WING FOR VARIEZE
In CP #20 we promised an update as to whether RAF would approve and recommend them. The testing we did manage to do last summer and fall proved unsatisfactory. The amount of work necessary to finish them

through paint is not significantly less than a good plans-built wing, and the weight savings is negligible if any. Also, we experienced structural cracks requiring repair. The attach system was inadequate, resulting in our having to destroy structure to remove the wings. It is possible that these problems could be solved but we have no current plans for further testing, thus, we cannot recommend their use.

ROTORWAY RW-100 UPDATE
You may have noticed that Rotorway has, once again, started their advertising blitz alluding that the RW-100 is now approved for the new Long-EZ. We understand there have been some changes in the engine and some further testing. However, we have not seen, nor do we have any first hand information on the engine as it is now. The advertising mentioning the Long-EZ/VariEze was done without our knowledge or consent and until we have had the opportunity to evaluate/test the engine first-hand we cannot recommend its use in any of our aircraft. We encourage new engine development and wish Rotorway success in their efforts. When the RW-100 is approved for Long-EZ/VariEze use it will be reported in this newsletter.

In our attempt to gather information on the acceptability of the Rotorway engines, we have been trying to access the reliability and maintainability of the helicopter version of the engine. If you know of a Scorpion owner willing to discuss his engine service record, please let us know his address so we can contact him. All information will be in confidence, we merely want to compile data on the engine's reliability.

BUILDER HINTS

Brake Cooling-
The "Real" George Scott reports brake overheating with his tight-fitting wheel pants. He has solved this by installing cooling ducts in his wheel pants to cool the brakes. He has detected no change in cruise airspeed, and has not experienced any brake fade since installing per sketch below. **SKETCH OMITTED**

Hotwire Templates-
An excellent way to make hot wire templates, is to glue the paper template to a clean piece of 1/16" thick aircraft plywood, available from Spruce or Wicks or hobby stores, using RAE or Safe-T-Poxy. Squeegee the paper onto the plywood and allow to cure overnight. Band saw or saber saw as close to the line as you can, finish to the line with a smooth metal file and/or sanding block. Lubricate the edge with pencil lead. This makes a really fine template with zero shrink. Do not use water base glue, it will shrink the paper.

Elevator Positioning
VariEze Section I, page 5-5 (or Long-EZ page 11-5) shows a smooth transition from the trailing edge of the canard onto the top of the elevator. This is not easy to attain, and still get full and easy elevator travel. It is acceptable to have up to 0.1" of "step-down" as shown below. However, be sure the slot shape and elevator shape are precise. **SKETCH OMITTED**

Yaw String

We have always flown our VariEze with a yaw string glued to the front edge of the canopy. This is used in sailplanes and is an excellent heads up yaw reference. Glue or tape a 3" long piece of yarn or string to your canopy leading edge, and be sure it is on the aircraft centerline. Mark the canopy where the string should lie in coordinated flight. **SKETCH OMITTED**

VariEzes can use the lighter Long-EZ canopy layup.
Save weight with an approved new layup schedule on your canopy. On the original VariEze the canopy layup is actually stronger and heavier than it really needs to be. New layup schedule is as follows for both the inside and outside layups: Front and back areas - 3 plies BID at 45 degrees. Side rails 2 plies BID at 45 degrees plus 2 UND lengthwise.

Prefab brackets available for VariEze.
The VariEze rudder belcrank brackets, Section I page 16-1 and 16-2 and A-4, have been slightly redesigned for Long-EZ and are available from Ken Brock and are applicable to a standard VariEze. Order 4 each part #CS71. Brock also has the rudder pulley brackets, Section I, page 16-1, order 2 each #CS72.

Long-EZ fuselage door
can be installed on VariEze, if you wish. See the detail reprinted from the Long-EZ plans.

The door shown provides a hole to reach through allowing you to fully lock the C-1 handle when you are outside your aircraft. The door also allows emergency canopy opening from the outside. Print the letters "EMERGENCY CANOPY OPENING" on the outside of the door. Apply the label shown on the inside of the door.

If you desire to install a key lock to secure your aircraft from radio theft, install a small drawer-type key lock (available from hardware stores). **SKETCHES OMITTED**

STROMBERG CARBURETOR
Last CP we reported a problem with a Stromberg carb in a VariEze. We have no experience with the Stromberg and had asked if any out there had used it successfully. We found 4 using the Stromberg carb ok but they reported that the float level is critical. Also the float valve opening is different for pressure and gravity systems. Be sure yours had the gravity valve. If you are anticipating using a Stromberg, we suggest you contact those using them in VariEzes.

Steve Stuff, 517 Roberts Street, Monroe, WA 98272	Gary Hertzler 2507 E. Balboa Tempe, AZ 85282
Fred Keller SRA Box 2385 Q Anchorage, AK 99507	Bruce Tuttle 4471 S. 1625 W. Roy, UT 84067

Float needle valve seat part # 384585 has a .113 dia. seat to accommodate 2-4 psi pressure at the carb. Part # 383911 has a .187

dia. seat for the half psi or gravity pressure at carb. (VariEze float level 13/32. For a C85-12 engine carb should be a NA-S3A1 Stromberg part # 380167, venturi 1-3/8, main discharge jet #22, main air bleed #66, main meter jet #45. But be sure the float needle valve seat is for the gravity system.

SOLUTION TO STIFF FUEL VALVES
One homebuilder reported his stiff fuel valve problems were solved by using a fuel valve lubricant called "parker fuel lube" available in most aircraft supply stores. Cost $10 or $12 for a small can. The lubricant is not soluble in fuel. This small can could lube dozens of EZs.

FUEL GAUGE VISIBILITY
Micro or traces of air entrapped in the fiberglass layup at the visual fuel gauge area will result in poor gauge readability. This is a very common problem, existing in a least half the airplanes we have seen lately. The gauge will read with excellent contrast only if the layups are perfectly clear. If you have not yet installed the fuel tank top, inspect your gauge area carefully. Without touching the surface you should be able to see your fingers clearly enough to count them when looking through the gauge. If it is not perfectly clear and translucent, cut out the gauge area, about 0.7" wide. Sand adjacent skin inside fuselage and out. Then layup two plies BID at 45 degrees onto two pieces of "Saran Wrap" (or glad-wrap) thin plastic kitchen plastic. Apply to inside and outside using your fingers on inside and outside to expel all air. The plastic wrap keeps the layup from drawing in air. After cure, remove the plastic. The result will be a gauge clear enough to see your hand through and will give a good contrast with fuel.

VARIEZE RUDDER TRIM.
The rudder trim as called out in the VariEze plans, is to enable you to correct any tolerance buildup that may cause your VariEze to yaw one way or the other. This system is intended to allow the pilot to set the neutral position of the left rudder at the position required for "ball-centered" flight. Most EZs trim with the rudder deflected left about 1/4" to 1/2". The rudder position for "ball centered" flight does not change with airspeed. However, due to airloads and stretch in the system from rudder to yaw trim system, the rudder blows toward the right at high speeds and slacks out to the left at low speeds. Thus, because of our trim system, trimming is needed when airspeed is changed. If we block the rudder itself, hard at the correct neutral position, we do not need inflight trim adjustment and we can seal the gap in the left rudder. Thus, inflight adjustment of trim when speed is changed is not necessary.

Proceed as follows: Visually note the position of the left rudder at cruise flight with the ball centered. Land, then block the neutral position there, with a balsa block epoxied to the winglet, closing the gap full span. Then fly with the yaw trim knob full in (inactive) to confirm position of the block. From now on use the knob only for parking brake function, not yaw trim. Or, completely remove the system if parking brake is not desired. Some EZ flyers use a small wheel chock instead of the parking brake, A nylon parachute riser attached to the chock allows you to haul it aboard when ready to taxi.

PLANS CHANGES
We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LCP #1, MAN-GRD, pg 21-8
The Bendix fuel pump called out does not have a means of safetying the bottom cap. This is done on certified aircraft as follows:
Bend the small tab shown 90 degrees, drill a #50 hole in it, safety with .032 stainless safety wire, tied to the fitting. **SKETCH OMITTED**

LCP #2, MEO, pg 19-10
Oops! We forgot to include the tie downs in the Long-EZ plans. Drill a 3/8" hole through the wings, 13" inboard along the leading edge, and 9.5" aft of the leading edge. This will assure that you do not drill through the shear web, but will be just aft of the shear web. Now flox a piece of aluminum tube into each wing, so that the tube is flush with the skins top and bottom. 3/8 O.D. x .049w 2024T3. Obtain two AN4 bolts and make up a couple of removable tie downs as shown These can be stored in the centersection spar when not in use. **SKETCH OMITTED**

LCP #3, MEO, Sect VI

See landing brake bushing revision below under VariEze plans change.

LCP #4, DES, Chap 7 & 21
See Safe-T-Poxy recommendation below for fuel areas.

VARIEZE PLANS CHANGES

MEO, Sect I, pg 18-3 & 19-11
Change "Nyloseal .050 wall" to "Nylaflow with .025 wall".

MEO, Sect VI
Landing Brake. Brock part #LB10 has been supplied with #10 hole. It should be drilled out with a 17/64 drill and a CS13 bushing should be inserted and clamped with the AN3-7A bolt as shown. **SKETCH OMITTED**

DES, Sect I, Chap 12 & 21
New construction only. The interior fuel tank layup and fuselage side layup should be done using only Safe-T-Poxy. Laboratory tests have shown Safe-T-Poxy to be more resistant to fuel than either Lambert or RAE epoxy systems. Our survey of possible fuel contamination (see CP #22 pg 7) did not reveal anything of major concern, although several of the 64 responding, reported a gummy substance on the float valve seat. Be sure to follow the CP #22 pg 8 Owners Manual carburetor inspection requirement.

MEO, Sect III
Radio Shack buzzer for warning is part #273-051

MEO, Sect IV
Under taxi testing add "Remove wheel pants for taxi tests to avoid overheating brakes".

VariEze Owners Manual, 2nd Edition pg 24, 3rd Edition pg 23
Add the following to pilot checkout criteria:
"5. Weight and balance must in the first flight box (pg 26/27).
6. Briefing must emphasize that the aircraft should never be rotated past the angle that places the canard on the horizon for takeoff or landing.
7. Pilot being checked out must have minimum of 10 hours each in at least two type aircraft in the last 4 months (5 in the last 30 days) & feel competent and comfortable in them during marginal conditions such as crosswind landings near demonstrated limits, etc".

VariEze Owners Manual, 2nd Edition pg 34, 3rd Edition pg 33
Add the following to aircraft first flight procedures:
"It is strongly recommended, if at all possible, that the test pilot have at least 10 hours VariEze experience or, at minimum, 10 hours in a small aircraft with a fast approach speed like a formula-one racer or other relatively 'hot' homebuilt".

FOCAL POINT - FIRST FLIGHT ASSISTANCE
The following VariEze builder/pilots have volunteered to give first flight assistance to any VariEze builder in their respective local areas. Many others have also done several first-flights on EZ's in their areas.

Steve Stuff Ray Cullen,

517 Roberts Street Monroe, WA 98272	1116 6th Street Tillamook, OR 97141
John Steicher, 960 86th Street, Downers Grove, IL (312)985-6671	Bob Woodall 8302 26th Ave, Adelphi, MD 20783 (301)422-6027

Thanks very much for offering your help, this is a much needed service and anyone else wanting to offer this kind of help should let us know, and we can publish names and addresses. With well over 200 VariEzes flying now, there is really no valid reason why a builder with no VariEze experience should have to make his first flight. We strongly recommend that any first flight of any new airplane be made by a pilot with at least 10 hours in type. Do take advantage of this from the many pilots who offer their skills and experience. A back-seat ride is not adequate checkout. Get the 10 hour front seat time or locate someone who has this experience.

"EZCALC" Electronic Instrumentation

The Long-EZ has such an impressive long range cruise capability that to fully utilize this unique efficiency we are developing an electronic unit that will give instantaneous fuel flow (gph) and average for the trip. This will also save panel space by displaying other engine data. Also displayed are: total fuel used/fuel remaining, fuel/distance/time remaining (pilot inputs ground speed), battery voltage, OAT, CHT, RPM, EGT, fuel low warning, clock local/Zulu, and approach timer. We installed a prototype in the Long-EZ for the trip to Sun-'n-Fun. We found it to be a invaluable aid in long range cruise control. For any given air speed and altitude we found we could lean for optimum and found my normal leaning technique was wasting fuel. An example, using my old technique at 180 mph true, I was using 6.2 gph, but using the "EZcalc" I could refine the mixture back to 5.56 gph for the same speed. Therefore we could easily exceed the advertised range for the aircraft. We learned a lot about leaning on the record flight using the Sears fuel counter and stop watch. But this unit gives a direct read out on fuel flow and you see it change as you move the mixture control. It's interesting to see the difference, with full rich at cruise power its 7+ gph and to be able to cut it back to 5.56 gph for the same speed is quite gratifying.

The "EZcalc" micro processor chip is now being designed and programmed for our special needs. There is a 15 week lead time on these new chips. We can expect availability of this unit by late summer.

ACCIDENTS

Since CP #23 there have been two off-field forced landings in VariEzes due to engine failure. No injuries, but both aircraft received major damage. The one in Southern California landed in the desert after the engine failed (reason yet unknown) taking the gears off and buckling the forward fuselage. The other in central California - engine failed just after take off when the pilot selected a tank with water in the fuel. (non-standard fuel system). The field was undulating soft grass. When the aircraft touched down it took the main gear off and

damaged the under fuselage and wings. The nose gear was not extended. Rain water got into the tank due to a very badly deteriorated "O" ring in the fuel cap. The aircraft had no gascolator or tank drains.

What is learned from the above? First, we don't recommend the nose be retracted for any landing no matter what the terrain is, even water. The nose gear provides extra cushion and keeps the nose from slapping down and digging in after the mains hit. The one possible exception could be brake failure after landing to retract the nose to keep from running off into unfavorable terrain or obstacles.

Water in the fuel system - - be sure the cap "O" rings are in good shape. Be sure all three drains are installed and used. If you suspect water, drain at least two quarts. Drain first while the nose is down from the wing tanks then from the gascolator with nose up. Some times it takes a lot of doing to get to the water. Run your engine at high power for awhile before take-off (nose up) to purge the water. Better to have it quit on the ground than just after take-off.

Don't be in a big rush to switch tanks. Have a safe landing area in sight before switching tanks if you can. Especially the first time you take fuel from the tank. In the case of water, even if you switch back to the "good" tank, you may not get it going in time. It takes a long time to purge water out of the carb. Also don't take short cuts on your systems, it takes a lot less time to do it right the first time than rebuild it.

Reference the Australian fatal VariEze accident reported in CP #23 page 7. We have learned that the pilot's total flight experience in the last 2 years had consisted of 1 hour solo and about 3 to 4 hours dual. He grossly over-controlled the aircraft in pitch on his first take off, flying at a relatively heavy weight at a relatively aft cg. Based on this and analysis of a previous accident with similar statistics, we are recommending additional limitations for the VariEze operators manual. These are listed in the VariEze plans changes section of this newsletter (page 6).

SHOPPING
NOTE! RAF cannot advertise complete or partially complete VariEze's, due to the inference that we have approved the quality. Our policy is that we will advertise your engines and propellers only.

TIRES: Both Aircraft Spruce and Wicks now stock Goodyear 6 ply ribbed tires. This has been the most satisfactory tire we have tested so far. We recommend them for both VariEze and Long-EZ. These tires should be inflated to 80 psi. Long-EZ now has over 240 HR on a set of these - they may go 300+ HR. Toe-in is 1/4 degrees.

HOUR METER: Both Aircraft Spruce and Wicks stock a VDO hour meter slightly different than the VDO 331-011 we recommended in CP #22. It is the same size and has the part # 1763-002-016.

Construction drawings for a VariEze trailer. We mentioned these in the Canard Pusher previously, and have received notice of a change of address. For more information contact:
C.A. Gross
6761 Crestview Dr.

Yucca Valley, CA 92284

Lloyd G. Eash, 541 Utah, NE, Albuquerque, NM 87108 has a disassembled Continental A-75 plus all kinds of parts for these engines. However, he does not want to piece-meal it, and would prefer to sell the whole lot to a VariEze builder. Contact Lloyd for prices.

For Sale - Brand new Ted's prop. 58" x 70" for C-90. $185.00. Alan McPherson (402)258-4212.

RAF NOW SELLS AND STOCKS EZ CANOPIES
RAF now has in stock at Mojave both new and slightly blemished canopies. These canopies are for both Long-EZ and VariEze. If you order one to be shipped to you it will be shipped FOB Dayton, Ohio. Or, save all shipping costs and pick one up at Mojave.

Prices are as follows:	Clear	$199.00
	Green	$229.00
	Smoke	$239.00
	Bronze	$239.00

Blemished - Price varies with extent of defect.

Note: Canopies are 94" x 25" x 13". If your car is not big enough, a canopy can be mounted to the top of the car with duct tape.

LANDING GEAR - RAF has both nose gears and main gears in stock for immediate shipment, or save yourself shipping costs and pick them up here at Mojave.

Prices are as follows:	Nose Gear	$49.75
	Main Gear	$277.95

These prices are FOB Mojave and these will be shipped freight collect. Generally we ship by Greyhound Bus, since the main gear is too large to go UPS. Shipping varies from approx. $10.00 to $26.00 on the east coast. Those of you ordering from foreign countries, please add $20.00 for shipping and handling. They will be shipped Air Freight collect from Los Angeles.

3-SHIP POSTER - The 18" x 23" poster we have for sale for $2.75 each or 2 for $5.00 plus $1.00 for postage is in color and is as shown on the cover of CP #22, consisting of Burt flying N78RA - the Defiant, Dick flying N4EZ - VariEze and Mike flying N27MS - VariViggen. This is a really excellent poster, printed from a beautiful photograph taken by Budd Davisson, and may be obtained autographed by the three pilots, or plain.

SANTA PAULA AVIONICS. Santa Paula Airport, Santa Paula, CA 93060 can take an Escort 110 and change it to an intercom and adjust it to draw only 0.6 amps very reasonably. Bruce Tifft recommends it, he has not had to charge his battery since.

OVERSEAS FOCAL POINTS
The purpose of this section is to list anyone willing to help other builders in their areas overseas.

Builders in France, contact -
Jaques Lesschaeve.
218 rue de la Rianderie,
59700 Marcq en Bardoeul
FRANCE

Builders in Switzerland, contact -
Rudi Kurth.
Langgasse 51,
CH-3292 Busswil
Switzerland

For any builder wishing to share shipping cost to Germany as mentioned in CP #23 contact -
Lt. Peter Maguson.
Post Fach 499
6541 Hatin Flug Platz,
West Germany.

When shipping the Main Gear to overseas customers, we have found that they ship better and take up far less space if wrapped individually rather than being boxed in quantity. To box the gear takes a great deal of time on our part and we do not have the facility to do so.

VARIVIGGEN NEWS
N27MS has been flown on several cross countries since the last newsletter, and has been trouble free. Ground speeds consistently are 160-165 mph with fuel flows of 7.5 to 7.9 gph. Sally and I have been very satisfied with our Viggen so far and would not trade it for any airplane flying.

Arthur Schwartz will be coming to Mojave in May to get checked out in the Viggen prior to flying his own. Once again, I encourage those of you Viggen builders who are ready to fly or close to it, to take advantage of our offer of a check ride before flying our own. I did it with Burt's Viggen and heartily recommend it. The difference of knowing what to expect and not having any idea, can really make the difference between having a totally uneventful and satisfactory first flight, and possibly damaging not only your airplane but your pride.

Lou Cislo in Hawaii reports good progress on his Viggen, although being so far from the "big island" means much delay in obtaining needed materials. B.W. Rottschaefer of Wyominssing, PA, reports that he lacks only installation of his cowling and paint and hopes to fly this summer. Frank Saunders from Miami, FL reports having repaired his beautiful Viggen after a gear up landing and should be flying again soon. Both Jack Rosen and Frank Stites report excellent progress and expect to fly this summer.

So much has been said in previous newsletters about the handling characteristics of the VariViggen, particularly the pitch trim change, with power changes, that I hesitate to go over it yet again, but since it apparently has been a problem for several Viggen pilots, we are more aware of it than most people. During some of my demo flights in the

Viggen I have taken off at minimum flying speed, then immediately forced it into a full-aft-stick climbing turn. From the pilot's seat this maneuver is not difficult, neither does it seem dangerous, however several observers from the ground have expressed concern over what would happen should the engine fail abruptly. Dick Rutan and I decided to find out.

I flew level at 5000 ft. at 60-70 knots, then went to full power to simulate a take-off, 500- ft. being the simulated field altitude. I 'rotated' as soon as possible and immediately began a steep climbing turn. Dick abruptly pulled the power to idle with no prior warning. We were 70-100 ft above our 5000 feet "runway", I countered the pitch up, rolled wings level, pushed over to pick up some airspeed, then flared to land at 5000 feet. Frankly I was surprised that this was easily accomplished. I had absolutely no difficulty in arriving at 5000 feet (ground level), wings level and with an acceptable sink rate. Of course in an actual situation such as we simulated, you would not be able to fly back to the runway, nor would you have time to lower the gear, so you would tear the airplane up, however it is a very survivable situation. Dick tried a few of the same maneuvers with approximately the same result.

My opinion is that a proficient VariViggen pilot will have no problem at all in handling a situation like this, which is, lets face it, the worst case you could encounter. However a low time, or low proficiency pilot flying a Viggen for the first time, probably would not be quick enough to counter the pitch up with less than acceptable results. One thing the test did prove, conclusively to me at least, was that the Viggen has more than enough nose down elevator authority. At no time during the tests did Dick or I ever require full forward stick.

Hopefully this will be the last word on the pitch trim change with power change. It is important to know about it. It is very easy to get used to, in fact after an hour or two in a Viggen I don't believe you would even be conscious of making adjustment to counter it. I certainly do it without conscious thought, and have never considered it to be a problem. Rather it is unusual, and therefore could catch an unprepared pilot. The main thing for the beginning Viggen pilot to remember is that if the engine fails or if power is abruptly retarded he must move the stick noticeably forward to maintain the same flight path.

FOR SALE - Lycoming O-360-A3A, 3 hours SMOH. Stainless exhausts, King radios, various instruments, and Viggen equipment. Send S.A.S.A. for list and prices to

John Poehner
409 Hillwood Court
Flushing, MI 48433

VARIVIGGEN PLANS CHANGE

The forward aileron cable attached to AB4, as shown in both first and second editions of the VariViggen plans interferes with the main gear when it is in the up and locked position. The best solution to this problem is to install the main gear before installing AB2's, AB3's and AB4's. Then install the belcrank assembly at an angle, such that the aft aileron cable attach point on AB4 remains at W.L. 4.6, but the

forward point is raised up 0.9. Check this on installation to clear your main gear when it is up and locked. The turn buckle called out to mount directly into the forward end AB4 assembly, should be moved inboard into the next bay (between WR25 and WR35.54), to ensure no interference between the turn buckle and the top of the main gear.

Bill Campbell is working on his outboard wings and reports the following mistakes in the second Edition of the Plans.

Chapter 8, page 29, part # WA1, B.L. 46.8 should be 47.3 and dimension 1.9 should be 2.4.

Composite Standard Wing chapter, Page A23, full size template at B.L. 114 (wing tip). F.S. of leading edge of template should be at 173.1 and therefore all fuselage stations from F.S 175 through F.S. 185 must be changed by one inch. Thus, F.S. 175 becomes F.S. 174, F.S. 176 becomes F.S. 175 etc. to F.S. 185 which should be F.S. 184. F.S. 188 through F.S. 199.75 are correct.

Thanks for pointing these two problems out to us Bill.

Viggen Builders add to your Owners Manual - Demonstrated crosswind component = 25 knots.

Several Viggen builders have wanted information to build and install a dynafocal engine mount. Since N27MS does have a dynafocal mounted O-360 Lycoming, I have taken some pertinent dimensions off it, which should help you to duplicate it. **SKETCH OMITTED**

CP24, Page 8

LONG-EZ PITCH TRIM SYSTEM, can be installed on a VariEze as an optional retrofit. Also, we are recommending it as standard for new construction VariEzes. The new system is a lever on the left armrest that actuates two springs driving the elevator tube on the left side of the fuselage. It has twice the authority of the previous system. Now you can trim hands off from the stall to over 160 knots. It is totally redundant from the normal pitch control system. If there were a failure of the pushrods or other pitch linkage parts, you could still fly home with the pitch trim. We have done approaches and landings without touching the stick, using throttle, rudders and pitch trim only. Install per the drawings shown. Retrofit requires removal of a portion of the left side console. Saw it out with a hacksaw blade, and patch with one ply BID tape. PTH and PTB are available from Brock. The springs are available from Aircraft Spruce and Wicks.

STEP 1
Mounting block - PT 1. Fabricate from 1/4" 5 ply birch plywood, see full size pattern. Locate PT 1, dremmel away the skin to clear the AN3 bolts (section A-A). Install the bolts, then bond PT 1 to the fuselage side with flox. Cover with 1 ply of BID that laps 1/2" onto the fuselage side, cure.

STEP 2

Fabricate PTH, PTB, and two PW's or purchase them pre-fabricated from the distributors. PTS (pitch trim springs) should be .350" outside dia. x .050 wire dia. cut to 6" (unstretched) and installed stretched to 9" long.

STEP 3
Cut two 20" lengths of 7 x 7 x 1/16" dia. aircraft cable. Using two AN100-3 and two 18-1-C sleeves, swage one end of each cable to PTH. Install PTH as shown using all the hardware shown in section A-A. Cut two 2" lengths of nylaflow nylon conduit and flox into instrument panel holes. Thread the cables through and swage the ends at the 5.6" and 6.2" dimensions with the PTH handle at the neutral trim position.

Rivet PTB to the VECS2 as shown using two AN470 AD-4-5 solid rivets. For new construction, be sure to do this before attaching this trimmed VECS2 to the left elevator tube. For retrofit, you can carefully squeeze these solid rivets using a vise grip. Do it progressively, a little at a time. Do not use pop rivets. Be sure to check for adequate longeron clearance.

Install AN100-3 thimbles in the PTB elevator bracket. Sew the PTS springs on as shown with two loops of .041 stainless safety wire. Now install the canard and hook up the springs. The elevator should sit at zero degrees with the PTH handle at neutral trim. Cut the required slot to allow full travel and mark the "take off" position. Leave a 1" dia hole in the console to allow adjustment of the lower bolt to change friction. Adjust friction to just hold PTH at full aft trim with full forward stick. Springs should never be slack. If your trim is insufficient at either end of the range, you can make a minor adjustment by shortening one of the PTS springs, up to a maximum of 1 1/2" shorter. If this is still insufficient, your elevator contour is incorrect. Further trim authority must be done either by correcting elevator contour, or by adding a fixed trim tab to the elevators.

WHICH ONE?

Rutan Aircraft Factory Inc., markets homebuilt plans for three different aircraft - The VariViggen, VariEze and Long-EZ. All three are two-place. The following information is intended to help you decide which is best for you.

PERFORMANCE AND UTILITY

The Long-EZ is the best in this category with range, altitude capability and performance way above the other two. Operation from high density-altitude airports at heavy weights is also best with the Long. The Long-EZ has the highest ceiling - a demonstrated 26,900 at light weights! Takeoff and landing distance of the Long is better than the VariEze and roughly similar to the VariViggen. Neither of the three are suited to unprepared fields, soft surfaces, gravel or small airports (less than 2000 ft, or 2400 ft with obstacles). Only the Long and Viggen are capable of night or IFR flying and only when properly equipped and flown by pilots with appropriate competence.

EFFICIENCY
The VariEze has the best miles per gallon, the Long coming in a close second and the VariViggen last. MPG at 75% power for the three are 35, 29, and 16 respectively.

CABIN/BAGGAGE
All three airplanes are soloed from front seat only. The VariViggen has two, similar, large, spacious cockpits with relatively upright seating. Large enough for 6 ft-5 in pilots. Two or three average-size normal suitcases fit the large baggage area aft of the rear seat. The cabin size and baggage room is much larger than the VariEze or the Long.

The VariEze and Long have two cockpits that are not similar. The front seat allows stretch-out comfort for pilots up to 6 ft-5 in, with carefully engineered thigh, lumbar, armrest and head support. The VariEze and the Long-EZ front seats are better suited to long-range comfort than the VariViggen seats. However, the VariEze and Long-EZ rear seats are smaller and less comfortable than the VariViggen. They can fit a 6 ft-4 in person, but comfort is compromised above 5 ft-10 in.

The Long-EZ baggage areas include two special suitcases, two cabin-accessible wing strake areas and additional room over the rear seat and in the wing spar. Total volume is nearly 10 cubic feet, however soft-type luggage must be used. Normal, hard suitcases do not fit. The VariEze has baggage room limited to the two special suitcases, approximately 3 cubic feet.

The VariViggen has center control sticks, rudder pedals and throttle in both cockpits, arranged much like a modern fighter. Conventional toe brakes are used. The VariEze and Long-EZ have side-stick controllers in both cockpits, but rudder pedals and engine controls only in front. Their rudder pedals work the two rudders independently and actuate the wheel brakes after full rudder is reached, i.e., one simple pedal for rudder and wheel brake.

CONSTRUCTION
None of the three require special skills or elaborate tools, since prefab parts are available for complex components. The VariViggen is by far the most demanding to build for several reasons: retractable landing gear, electric aileron reflex controls, full dual cockpit controls add a considerable number of parts to build. The mix of wood and composite structure requires different skills and tools. Control system includes many parts. Total building time can run from 3000 to 4000 hours, approximately 3 to 5 years of spare time effort.

The VariEze has been built by homebuilders in as little as 550 man hours and 4 months. However, projects on the average run closer to 900 to 1200 man-hours and 1 to 1.5 years spare time. The Long-EZ requires about 10 to 20 percent more work than a VariEze.

Any of the composite work (complete Long-EZ, VariEze and VariViggen outer wings) requires a clean shop that is controlled to a temperature range of 70 to 90 degrees and that allows work without direct sunlight on the part being built. Minimum shop size for Viggen, Long and VariEze is 400, 300, and 250 sq. ft. respectively.

ENGINE SIZE
The VariViggen, designed for the 273 lb 150 hp Lycoming is limited to the 150, 160, and 180 hp Lycoming engines. The lightweight, fatigue-free fixed pitch wooden props must be used. Heavy metal props make it (and the VariEze and Long) tailheavy, and increase risk of prop failure. Use of the 180 hp or injected 160 hp Lycomings on a VariViggen will result in a requirement to carry nose-ballast.

The Long-EZ is limited to the Lycoming O-235 (108 to 125 hp) and Continental O-200 (100 hp) with any accessories. The Lycoming is preferred, since it has a fuel pump and longer overhaul life.

The VariEze is intended for the lightweight Continental A75 and A80 engines. The C-85, C-90 and O-200 can be adapted, but they must be stripped of accessories to avoid an overweight, tailheavy airplane.

STALL CHARACTERISTICS
All three aircraft are designed to be "stall proof", i.e., they can safety maneuver up to, and including, full-aft-stick without experiencing a stall break, departure, or loss of altitude. They can all climb at the full-aft-stick speed, Long-EZ being the best (900 ft/mn at gross), Viggen the least at about 400 ft/mn. Homebuilder experience has shown that most VariEzes have excellent stall characteristics but a few experience wing rocking and roll-off at the stall. This is not expected with any of the Long-EZs, since they were designed with a greater margin of stall for the rear wing. Our prototype Long has proved to have exceptionally docile high angle attack characteristics, resisting departure for any maneuvers including tailslide stall entries, and application of all combinations of rudder and aileron. The VariViggen also has a good stall margin, with its standard wing configuration, however, with its special performance-wing its stall margin is low, resulting in more conventional characteristics, i.e., at minimum speed the S.P. wing will drop if the pilot sideslips.

MANEUVERABILITY
The VariViggen excels here, with its high roll rate and tight turning capability. However, due to its low aspect ratio, the Viggen looses speed in maneuvering. Thus, for sustained maneuvering, the Long is the best - it can climb over 400 ft per minute while maintaining 2-g at gross weight! The VariEze has the lowest roll rate. All three types are noted for their good maneuverability, as compared to conventional aircraft.

PILOT SKILL REQUIRED

The VariEze's high approach and landing speeds and responsive controls put more demands on pilot proficiency than the Viggen or Long-EZ. The Viggen has a relatively large trim change with power application. (nose up when power is reduced), requiring pilots attention. The VariEze and Long-EZ have very small trim changes for power, gear extension and landing brake extension. A VariEze or Long-EZ can fly for extended periods with "hands-off" controls. A Viggen must be continually flown. For those reasons the Long is the most docile, easiest for fly, and safest for the low-proficiency pilot.

Crosswinds - due to its responsive roll rate, high available sideslip and wide landing gear, the Viggen can handle the most crosswind. Takeoff and landing in wind components well above the capabilities of conventional airplanes are relatively easy. The Long-EZ is next, capable of handling a 20-knot component. Due to lower roll rate and lower wing tip clearance, the VariEze is last for crosswinds.

VISIBILITY
In order of preference - Viggen, Long and VariEze.

COST
Refer to the respective sheets for a breakdown of costs to build each airplane.

LONG-EZ

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE
The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As

compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE
At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY
The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to 27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES
Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

VariEze

FAST - EFFICIENT - FUN

PHOTOS OMITTED

THE AIRPLANE
The VariEze is a small, high-performance homebuilt sportplane. It is recommended for day VFR operation only. The power plant is the A-75 or A-80 Continental. The airplane is not alternator equipped. A basic electrical system can be installed to run a NavCom and standby gyro instrument. This electrical system is powered by a solar panel and/or ground-charged. Additional electrical instrumentation, electrical engine starter, and night lighting are not recommended.

Larger Continental engines, up to 100 hp (C-85, C90 and 0-200) can also be used, but their accessories must be removed (starter, alternator and vacuum pump) to provide adequate useful load and proper aircraft balance.

Cockpit layout is a sidestick on the right console, rudder pedals/brakes and throttle and optional landing brake on the left console. A backup sidestick is located in the rear cockpit. A small amount of baggage can be carried in two special suitcases.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core, reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite-sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

EFFICIENT DAY-VFR UTILITY
In addition to fun recreational flying, the VariEze can be used for VFR cross-country flying. Its range, single place, using the full 26-gallon fuel supply is 750 miles plus 45 minute reserve. Two place, with 15 gallons fuel, the range is 430 miles plus 45 minute reserve. Economy is excellent - 35 mpg at 177 miles per hour and 42 mpg at 140 miles per hour. Complete range and performance data is shown in the Owners Manual.

UNUSUAL EFFICIENCY
The VariEze uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. At light weight, a VariEze powered by an 0-200 has climbed to over 25,000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane.

GOOD FLYING QUALITIES
Development of the VariEze included flight testing of many refinements to optimize flying qualities. It is a solid, stable airplane that has responsive elevators and ailerons, good turbulence response, excellent "hands off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or

spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries. Climb is excellent, even at the full-aft-stick speed. Trim changes due to power, gear retraction or landing brake are all very small. It's cg range allows a range of pilots or passengers weighing from 150 lb to 220 lb. Lighter pilots generally require the addition of ballast. The VariEze's approach and landing speeds are 85 mph (75 kts) and 70 mph (60 kts) at normal landing weights. The approach and landing are at a faster speed than average light planes. Forward visibility is inadequate, thus, the airplane is landed at about 10 knots above its stall speed. Pilots should be competent and proficient in several types before VariEze check out.

THE HOMEBUILDER SUPPORT
The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan Newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was one of the most extensive ever conducted on a homebuilt. It included basic flight test for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop test exceeding part 23 criteria, environmental/thermal test on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,500. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mount to small aluminum brackets and bushings can be purchased from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a VariEze in as little as 700 man-hours. The budget minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. A partially runout A-75 can cost as little as $1500. Newly overhauled engines can cost from $2000 to $3500. Engine accessories, such as instruments, prop extensions etc cost about

$300 to $500. In summary, the total cost can run from $4300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $8500 for everything available purchased and a zero-time engine.

VARIEZE DOCUMENTATION is available in six sections.

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also the complete plans and construction manual for the VariEze except engine installation. The manual consists of a 153-page, bound 11" x 17" book plus nine larger full size drawings. It includes 168 photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane. The manual identifies sources for all materials and all prefabricated components. NASAD approved.

SECTION IIA - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

SECTION III - ELECTRICAL - This is an optional (not required) set of drawings and installation instructions for electrical system.

SECTION IV - OWNERS MANUAL - This is an operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

SECTION V - FINISHING THE COMPOSITE AIRCRAFT - Applies not only to a VariEze, but to other epoxy/composite aircraft. Includes filling/contouring priming/U.V. barrier/color and trim.

SECTION VI - LANDING BRAKE - Complete full size drawings for an optional drag device. The brake dramatically increases the airplane's glide angle and deceleration in the flare. Without the brake the airplane is limited to runways at least 2400-ft long. With it, runways down to 1800-ft can be used with appropriate pilot proficiency.

VARIVIGGEN

FULLY RETRACTABLE, FIGHTERLIKE, HIGHLY MANEUVERABLE.

PHOTOS OMITTED

EXCELLENT UTILITY.

Comfortable tandem cockpits, three-suitcase baggage area, and an adequate cruise speed provide unusual utility for a homebuilt airplane. It's road-towable with outer panels removed.

PROVEN DESIGN
Complete flight test program completed; 600 hours on prototype with very little maintenance. Won the Stan Dzik trophy for design contribution, Oshkosh '72, the Omni Aviation Safety trophy at Oshkosh '73 and the outstanding new design award at Oshkosh '74.

STALL/SPIN SAFETY
The VariViggen's safe flying qualities have been the subject of technical presentations for EAA, SAE, AOPA, and AIAA. It will not stall or "mush in" like the common delta. At full aft stick (43 kts) it will still climb 500 fpm, roll over 50 degrees per second without rudder co-ordination, and make buffet-free turns. The standard-wing VariViggen is highly stall/spin resistant. The Special-performance VariViggen can be stalled if sideslipped at low speed.

FLYING QUALITIES
The Viggen flies similar to conventional aircraft, with the following exceptions: higher roll rate, ability to tightly maneuver without stall, and trim change due to power change (nose rises unless checked when power is reduced). The Viggen can handle crosswinds that exceed the capability of conventional light planes.

UNCOMPLICATED DESIGN
The basic structure requires few special tools and can be built in a simple jig. The few parts that have double-curvature are available in fiberglass, ready to install. All machined and welded parts are available. Due to the many systems and wood structure, building time is not short. Allow 3000 to 4000 man hours.

COST TO BUILD
Raw materials - approximately $3000. Prefab parts - approximately $2800. Engine - $500 to $3500. Instruments - approximately $500. Total cost can run from $6000 (owner built prefab parts and half run out engine) to about $9500, plus avionics.

THE FOLLOWING DISTRIBUTORS MARKET VARIVIGGEN PARTS.

AIRCRAFT SPRUCE AND SPECIALTY CO.
Box 424, Fullerton, Ca 92632
(714) 870-7551

Special Performance Wing	Gross Weight	1700 lb.

The following documentation is available:

VARIVIGGEN TECHNICAL REPORT. Complete tech. report describing the VariViggen two-place sportplane. Includes specifications, pilot report, dimensions, 3-view stability and performance flight test data. Description of car-top wind tunnel. 8" x 10" glossy photo and current issue of newsletter. Price - $10.00 first class mail, $11.50 Airmail overseas.

VARIVIGGEN OWNERS MANUAL. Complete operational handbook including normal and emergency procedures, loading, operational record keeping. Price - $6.00 first class mail. $7.50 Airmail overseas.

"CANARD PUSHER" SUBSCRIPTION. A newsletter designed with the builder in mind. Emphasis on distributing to all builders as many ideas, improvements building tips, photographs, and flight reports as possible. Details mandatory, desirable, and optional changes to plans and to owners manual. A newsletter subscription is mandatory for those with VariViggens under construction. Published quarterly. Price - $6.75 first class mail. $8.75 Airmail overseas. Back issues, $1.50 each.

VARIVIGGEN PLANS - SECOND EDITION. This is an updated, revised set of very complete drawings and construction manual consisting of a bound 11" x 17" book, containing many photographs, hints and instructions based on actual builders experience over the past several years. It covers the entire airplane, including the engine installation, fuel system, and not only covers the original standard wing in both aluminum and foam and fiberglass composite, but it also includes the composite S.P. wing, ailerons, and rudders. The manual identifies sources for

all required materials and all available prefabricated parts and components. Price - $165.00 first class mail. $177.00 Airmail overseas

VARIVIGGEN R/C MODEL PLANS. Complete construction plans for the 18% - size radio-controlled model airplane built and flown to evaluate VariViggen spin characteristics. Designed for 4-channel proportional radio equipment and engine in the .35 to .65 cubic inch size. 555-sq inch wing area. Price - $4.75 first class mail. $5.50 Airmail overseas. Note - Add 6% tax for California orders.

THE CANARD PUSHER NO 25 JULY 80

Published quarterly (Jan, Apr, Jly, Oct) by
RUTAN AIRCRAFT FACTORY,
Bldg 13, Mojave Airport,
Mojave, Ca 93501
(805)824-2645

U.S. and Canadian subscriptions	$6.75
Overseas (AIRMAIL)	$8.75
Back Issues	$1.50

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 25. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 25. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 25. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 25. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 and 25.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

Saturday Demos - Every Saturday (except as shown below) RAF conducts a demo at our shop at the Mojave Airport.

We start the presentation/discussion at 10 am each Saturday with flight demos of our experimental aircraft at approximately noon (weather permitting). This will be done each Saturday except when we will be gone to the following airshows:

2 Aug	80	Oshkosh, Wisc.	EAA Convention
9 Aug	80	Oshkosh, Wisc.	EAA Convention
4 Oct	80	Tullahoma TN	EAA Convention

Bring any of your parts for inspection. We are located near the west end of the flight line at the Mojave Airport about 2 hours drive north of Los Angeles on Highway 14. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question.

Mark the outside of your envelope "builder questions". This will speed your reply.

RAF ACTIVITY - Since CP 24 has included development of grassfield/rough field capability for the Long-EZ, development of a fuel pump system for the O-200, new pilot checkouts in the Long-EZ, finishing up the Long-EZ owner's manual, and several consulting jobs.

LONG-EZ/VARIEZE PREFAB GLASS PARTS
We are very pleased to report that our new manufacturer is in production on nose wheel wells, strut covers, sump blisters (Long-EZ) and cowlings. He is also working on tooling for wheel pants and looking into making tooling for wing tanks (strakes) on both VariEze and Long-EZ.

The quality of all the parts is outstanding. The first new parts will be shipped to our suppliers starting July 7th. The tooling has been completely redone and is first class. The cowls, direct from the mold are shiny white gel coat finish and may not even require paint.

LONG-EZ OWNER'S MANUAL
The Owner's Manual is now available from RAF, and is an excellent place to go for Long-EZ performance, range, etc. Note: unless otherwise specified all speeds shown in the manual are in KNOTS.

NOTE: RAF WILL BE CLOSED 1 AUGUST 1980 THROUGH 12 AUGUST 1980 FOR OSHKOSH.

FIRST HOMEBUILDER'S LONG-EZ FLIES!!
Johnny Murphy, that prolific builder pilot from Cape Canaveral, Florida is now flying his Long. He and son Steve plan a non-stop flight to Oshkosh 80, weather permitting. Johnny has built one of the first VariEzes and Quickies also!

The adjacent photos show the six-g static load test Johnny conducted on his Long to assist RAF in confirming the structure. Strain gages confirmed only about 50% of allowable stresses were reached at six-g, with a wing tip deflect of 8.5 inches (21.6 cm).

He also reports it holds 55 gallons of fuel and gets off in 700 feet on a hot day with full fuel. Johnny says his Long is faster than his VariEze.

As of July 2nd, Johnny has eight hours on the airplane and has had three other pilots fly his Long, because he says it is "so easy to fly".

PHOTOS OMITTED

DICK AND MIKE'S LONG-EZ's By Mike Melvill
We like the Long-EZ so much that Dick and I decided to get together and build two of them. We rented a building, fabricated a couple of tables, the wing jigs and centersection spar jig and ordered complete raw material kits from Aircraft Spruce and complete prefab parts from Ken Brock. We picked up the parts and materials on June 14th. Since this is our own project and we are doing it as a recreation and hobby type thing, we only work on them during our spare time, after work and

weekends. Today, 12 days after receipt of kits, we have two fuselages assembled and glassed on the outside with speedbrakes and are laying out centersection spar parts. We are building them as quickly as possible, as we both want them for economical transportation machines, and we would like to have them flying as soon as possible. Neither of them will be "Grand Champion Quality" by any stretch of the imagination, rather they will be "plain vanilla" Long-EZ's built as light as possible to be flying as soon as possible. I have obtained an engine already, a Lycoming O-235 L2C, 118 hp at 2800 rpm out of a wrecked Cessna 152. Unfortunately this engine is not ideal for a Long-EZ in that it does not have a fuel pump, and does have a full-flow spin-on oil filter. The filter projects 1" into the centersection spar, and a fuel pump is mandatory on a Long-EZ. I am currently looking for an O-235-C accessory case! The O-235 L2C come as above only from Cessna 152's. The same engine from a Piper Tomahawk or Grumman trainer is fine and does have the fuel pump. Dick is still looking for an engine for his Long-EZ. We will continue to report progress on our two Long's in future Cps.

HOSPITALITY CLUB FLYINS

Kern Valley Airport, Kernville, Ca
May 31st - June 1st.
Twenty five member airplanes flew in from all over the west. The weather was great, the campsite good, the hospitality provided by the airport was outstanding, extending to a really excellent bacon and eggs breakfast grilled out doors on Sunday morning.

The "dawn patrol" certainly woke everyone up with fly bys over the campsite, much too early for me at least!

Burt and Dick's grandfather, Mr. Goforth, 91 years old, went for his first ride in a small plane when Dick took him up in the Long-EZ. Several people sampled the thrills and "chills" of the whitewater in the Kern River, and good times were enjoyed by all.

Saturday evening was the highlight. We all went to dinner at the "Ewings" restaurant in Kernville and after a little dancing, returned to the airport where Bill Brackett gave a most enjoyable impromput show. Bill is a talented musician and a very funny comedian.

Once again, the Hospitality Club flyin proved to be really outstanding.

Burt's Surprise Birthday
June 21st
Mojave Airport was the sight of the most recent Hospitality Club flyin. Burt was kept in the dark about it and was not aware of anything until he drove in at around 11:30 am on Saturday morning. There were 25 VariEzes parked in front of the RAF hanger, surprise!!!

Several people flew in from considerable distances, Norm Ross from Victoria, Canada, Charlie Richie, Los Cruses, NM, and Gary Johnson from El Paso, TX to name a few. The San Diego contingent arrived in style

with a 5 ship flyby. They have 14 VariEzes flying and 28 under construction in the San Diego area!

An excellent chicken dinner was catered in the RAF hangar; where much "hangar flying" was conducted. Over 120 people flew or drove in, and again a great time was had by all.
Dues - Just a reminder, the dues for the club are $4.00 State side and $6.00 overseas.

VARIEZE HOSPITALITY CLUB FLYIN TO THE BAHAMAS
Bruce and Bonnie Tifft have been really working hard in getting all the information together for this Christmas trip. The plans are pretty well firmed up and for further info, please send a self-addressed-stamped-envelope to Bruce and Bonnie. The dates planned are December 27, 1980 through January 2, 1981. Blanket oks have been approved for VariEze flights to the Bahamas.

Bruce and Bonnie Tifft
8746 Ventura Ave,
Ventura, CA 93001

LBF RACE OSHKOSH 1980
We are looking forward to a great VariEze race this year and some interesting competition. It's not an all out full bore but a strategy race getting the most speed out of the least amount of fuel. Even if your EZ is not as fast as some of the others you still have a good chance of winning by good fuel management. So don't let that stop you from entering. If you haven't done so call the race director Mr. Aaron King immediately (404)355-6185 to get registered, the dead line is short.
Or write to: Aaron King
1893 Graystone Rd,
Atlanta, GA 30318
We have established a VariEze/Long-EZ class within the race with a $1500 cash purse to be split between the three best VariEze/Long-EZs. This is in addition to the $9000 purse given by the race organizer. For rules see page 14 in the May 1980 issue of Sport Aviation and CP24.

The following VariEze class sponsors each contributing $250 are Applied Plastics (epoxy formulations), Aircraft Spruce, Wicks Aircraft, Ken Brock Mfg, Herb Sanders (exhaust), and Rutan Aircraft. Plus any more I can line up before race time. Applied Plastics will also donate a safety laminating kit to each entry.
Don't delay do it now time is short. See you at race time.

PROPELLERS
We are happy to announce a new propeller company to add to our list of recommended propeller manufactures.

The Great American Propeller Co.
555 West Mont Drive #212
San Louis Obispo, CA 93401
(805)481-4450

We evaluated their 56 x 68 on the VariEze prototype N4EZ Continental O-200 and found it's performance to be as good or slightly better then anything we have tested so far. The quality of workmanship of the prop is excellent and should give good reliable performance.

We have been working with Bruce Tifft "B & T Propellers" trying to optimize a prop for the O-235 powered Long-EZ. We just completed an evaluation on his 60 x 66 prop and found a significant improvement in cruise speed (5 mph) without a loss in climb performance. Note, our airplane now is flying faster then the Owner's Manual data. Bruce's quality of workmanship is excellent and his unique leading edge protector make it impervious to rain erosion. Bruce's extra effort in this area is appreciated very much.

B & T Propellers
8746 Ventura Ave,
Ventura, CA 93001
(805)649-2721

MECHANICAL FUEL PUMP FOR LONG-EZ

The Long-EZ fuel system must have a mechanical fuel pump. The gravity fuel system used on the standard VariEze will not work on the Long-EZ. Most O-235 Lycomings and the Rolls Royce O-200/O-240's have pumps. The Continental O-200 and some Lycoming O-235's that came out of the high wing Cessnas don't have mechanical fuel pumps nor are the cases machined to accept them even if you had a pump in hand. So if you are looking for an engine be sure it has a mechanical pump. However, if you have a "blue" high wing Cessna engine you can adapt a pump by one of the following methods.

1. The most preferred method is to have the cases machined and install the cams and push rods as necessary to convert it to a standard mechanical fuel pump configuration. Check with a certified engine overhaul shop for the conversion. This method requires total engine tear down. The machining and parts are expensive. If the engine is in for overhaul have the modification done before reassembly.

2. We have been told that a Thompson Vane Type pump series # TF1900 will mount on the vacuum pump pod and provide the necessary fuel pressure. But we have not tested it. The pump is a standard aircraft pump with A.N. fittings but must be adjusted back to a lower 2-8 psi pressure. The pumps are somewhat expensive, but available. Contact Dick Davy at Precision Aero, 2749 E. Wardlow Road, Long Beach, CA 90801, (213) 595-6377 for the Thompson pump.

3. We are working with Rex Taylor from H.A.P.I. V.W. engines to adapt a Volkswagen fuel pump to run off the vacuum pump pad. We have a prototype of this conversion in service test on N4EZ and it's working satisfactorily at this time. However, the V.W. pump has automotive fuel lines, not aircraft A.N. fittings. This will be the least expensive method. Rex is also working up an adapter to run a standard aircraft AC fuel pump off the vacuum pump pad. You can contact Rex directly by calling (714) 357-6342. Note: This method is still in the development stage and may not prove satisfactory. We should have something more definitive next CP.

VARIEZE BOAT-TAILED EVALUATION

There has been a lot of interest in the "boat tail" since Steve Woods ran his in the VariEze race at the Sun-n-Fun. We obtained a boat tail shell from Ken Forrest and ran a very close evaluation to determine if there was any performance advantage to this modification. Our evaluation with and without the boat tail shows no perceptible difference in performance.

Steve Woods also has a NACA engine air cooling intake scoop which involves extensive additions to the fuselage and cowl. Steve has asked to make it clear that the flush scoop will not adequately cool the engine. Steve had to develop extensive baffling modifications to get the good cooling he now has. We are following Steve's developments and are particularly interested in his cooling baffle configuration.

MODIFIED LONG-EZ NOW APPROVED FOR GRASS FIELDS

Rutan Aircraft has recently tested a spring loaded "shock strut" which was installed in place of the NG-9/NG-10A rod on Long-EZ. This, combined with 500 x 5 main tires, was tested by progressively taxiing over 1" x 2", 2" x 4" 's and finally over two 2" x 4" 's, one on top of the other. The results showed a very significant increase in the rough-field absorption qualities of the landing gear. Taxiing over stacked 2" x 4" 's resulted in very acceptable loads, with a satisfactory ride.

We then flew N79RA to a average grass strip and conducted takeoffs and landing at a range of weights and cg positions. Also, taxi test in tall grass and undulating surfaces was satisfactory. A Long-EZ with the spring strut and 500 x 5 main tires is now approved to operate from average grass fields. This does not mean it is acceptable for gravel or unprepared/rough surface. The prop damage that can result from operating on gravel is unacceptable.

The spring strut is installed by simply removing the 2 bolts on the NG 10A pushrod and replacing it with the spring assembly. Additional clearance is required by trimming away a portion of the strut cover.

The spring is intended primarily for the Long-EZ, to give it the grass capability, however VariEze owners may want to install it to improve the rough field handling of the nose gear. The spring allows the gear to deflect aft and up when a bump or hole is encountered, and greatly reduces the loads on all parts (strut, NG10A, castings fork and wheel). The Long-EZ fiberglass strut is stiffer than the VariEze, thus the new spring is strongly recommended unless you plan to always operate from smooth surfaces. Without it, nose gear damage may occur from rough surfaces.

Note: This is not intended to provide grass field capability for the VariEze. Its faster takeoff/landing speed and inability to use 500 x 5 tires makes it unacceptable for grass.

The strut, ready to install, is being made available by Ken Brock. Ken will also stock the LST-6 spring for those wanting to build their own. Refer to the drawing in this newsletter. Several different spring configurations were tested until arriving at the 1.5 x 4" heavy duty

rectangular coil spring. If building your own, shim as required to obtain the specified 250 lb preload. The strut should not deflect when static with pilot in cockpit and full fuel.

A FUNNY THING HAPPENED ON THE WAY TO EZ COMPLETION
By Jud Bock Serial #738.
While doing some finishing work in the back seat, I decided to close the canopy to check the rear head rest. It felt great, so I went to open the canopy and lo and behold the safety catch in the front cockpit was working perfectly! There I was, all 210 lb of me, locked in the back seat with no tools or anything to reach the 4" more, required to release the catch. My wife had just gone shopping and was not expected back for three quarters of an hour. Did I panic? Hell yes, because I was getting warm (hot actually!), and I decided to use my head and tried to use mind power to move the catch. After that failure, I started thinking some more and it finally dawned on my dulled brain that I had shoes on, which I promptly removed one of and was out in less than 5 minutes.

In another instance the builder has no shoes on. He removed his pants, rolled them into a stick and used it to reach the catch!

With consideration of this problem we designed the safety catch to be mounted at F.S.57 on the Long-EZ. VariEze new construction should follow suit.

BUILDER ASSISTANCE
More names to contact for builder assistance:

Al Coha,
5173 Leo Street,
San Diego, CA Phone: 582-2137

Nat Puffer,
???? N Payne Ave,
St. Paul, MN 55117

Nat is also willing to check new EZ pilots out in his VariEze, and to do first flights in new EZ's, limited runway flights, but not including envelope expansion.

CHECK OUT EXPERIENCE IN THE LONG-EZ
To date 30 pilots have been checked out in the Long-EZ. Pilot experience ranges from student, private, military, aviation writers, VariEze and even the odd airline captain. No problems were encountered by anyone and all made the transition easily.

Pilots current in a VariEze were given ground systems briefing and turned loose. The more experienced pilots without VariEze time were given one turn around the pattern (instructor in the back) then turned loose. Since the Long-EZ has a more solid pitch response and a lower deck angle on landing than the VariEze there was much less pitch bobble and no high round out landings as in some VariEze check outs. There was still some tendency to push both rudders out, especially on the first take off, but since you don't couple to roll as much as the VariEze this never created a problem. The most common comment was how

long it took to slow down to pattern airspeed and how much it would float on landing especially if you were fast.

We check out and soloed two of our RAF low time pilots, Sally Melvill (Mike's wife) 150hr private pilot and Pat Storch (Burt's girlfriend), a 24 hour student pilot. At no time did the instructor need to take control to save/recover the aircraft. Both were soloed after 1.5 hours dual in the front seat (6 to 8 landings). Neither had any formal backseat dual. Since the instructor had no throttle or brakes in the back, enough time was spent on the ground making low/high speed taxi runs to be sure this area was mastered. Neither required more than 10 minutes in this area.

Sally is current in a Champ, Grumman Tiger and VariViggen. Pat had only flown the Tiger. Both girls are exceptional pilots, better capable than average for their flight time. The following is Pat's personal perception of her flight:

"Incredulous - that was my first feeling when they told me they wanted me to solo the Long-EZ. Tiny insecurities worked their way out in the form of protests. "But I'm only a student! I've only soloed one other airplane! I have less than 25 hours!" It seemed that I was the only one lacking in confidence, because they would not be dissuaded.

The day came when it was time to give it a try from the front seat. The cockpit looked foreign, almost hostile. Instruments were not where my eyes wanted them to be. Throttle and stick were in the wrong hands. With my heart in my mouth, we started the pattern work. Soon I was thankfully too busy to be nervous, but I still felt I was reaching for an unattainable goal. Control of the Long felt so different, and the full-stall landings I had practiced so diligently in the Tiger were to be forgotten.

Then, amazingly, little pieces started falling together. Each landing felt better, the cockpit looked more familiar and a tiny seed of confidence started to bloom. Could it be? Would it really happen? Down to refuel and then came the words I wanted to hear - "you're ready to go!". My heart was racing once again but this time it was from anticipation and excitement. Lined up on the runway, I took a deep breath and was rolling. The take-off was smooth and felt good. The plane felt fantastic. I played in the sky. Up, down, around, turns and steep turns to 2 g's. I never expected any experience to equal my first solo, but this surely surpassed it. Flying never felt so good! Then came the final test, the landing. A little long, but a good one.

A Long-EZ pilot! I flew the Long! I wanted the world to celebrate with me. Flying had taken on a new dimension. I may have landed, but I was still in the air, and haven't come down yet. What a satisfying, exhilarating experience".

CAUTION - AMATEUR DESIGN
In 1977 an amateur designer/builder highly modified a VariEze with all-flying canard and other modifications. It crashed on its first tests, injuring its designer test pilot. Recently a new design, with the outward appearance of a VariEze, crashed on its first flight attempt, killing the pilot (a professional Cessna test pilot).

If you are contemplating a new design or modifications to an existing design be sure you understand that aerodynamic design, particularly for tandem wing configurations, is an engineering discipline that requires the appropriate analysis and test before risking ones life.

RETRACTABLE LANDING TAXI LIGHT INSTALLATION DRAWINGS FOR LONG-EZ - are new being shipped with Long-EZ plans. If you did not get this drawing with your plans, send a self-addressed-stamped envelope to RAF. This drawing is too large for the newsletter.

CONTINENTAL O-200 OIL BREATHER
Last winter we modified the configuration of the oil separator and location of breather outlet on N4EZ. This configuration is successful in scavenging all oil - none spills out the breather. It is plumbed as follows:

SKETCH OMITTED

BAFFLE HOLE IMPROVES CONTINENTAL ENGINE COOLING
Several VariEze owners have opened up a hole in the left-front baffle to improve cooling of the #1 cylinder exhaust port area (Continental only). This is in a position where, due to the locally low height of fins, the baffle does not otherwise allow enough airflow. See sketch. This hole allows direct impingement of cool air on the head just above the exhaust port. Center the hole over the area that is devoid of fins.

SKETCH OMITTED

OPTIONAL LONG-EZ LAYUP CHANGE SAVES WEIGHT
The following approved layup change on the Long-EZ centersection takes advantage of the better structural efficiency of oriented UND as compared to woven BID. These changes are easier to layup and save 3.5 lb weight!

Page	Layup	Old	New
14-2	5	3 Ply BID @ 45degrees	1 Ply UND @ 45degrees 1 Ply UND @ -45degrees
14-3	6	3 Ply BID @ 45degrees	1 Ply UND @ 45degrees 1 Ply UND @ -45degrees 1 Ply UND @ 45degrees 1 Ply UND @ -45degrees
14-4	8	3 Ply BID @ 45degrees	1 Ply UND @ 45degrees 1 Ply UND @ -45degrees

Note: UND cloth is butted, not overlapped at selvage edges. Be sure alternate plies of UND cross at 90 degrees fiber orientation to each other.

FIREWALL - LONG-EZ AND VARIEZE

We now approve the use of fiberfrax (a space age ceramic material) as a replacement for asbestos. Since fiberfrax is as good a fire barrier as stainless steel, we approve substituting .016 2024 T-3 aluminum for the stainless. This saves almost 2 lb at the firewall. Both Wicks and Aircraft Spruce are now shipping kits with fiberfrax and aluminum.

Installation of fiberfrax is as follows: Complete airframe construction through cowling installation, then remove everything from the firewall bulkhead, and install fiberfrax with a bead of silicone around the edge of the bulkhead. Do not wet out fiberfrax with epoxy. Now install the .016 2024 T-3 aluminum which is required to protect the fragile fiberfrax, from local damage, abrasion etc. See plans changes section of this newsletter.

VARIEZE FUSELAGE TANK VENT CONFIGURATION
Al Coha reports that unacceptable low pressure on his flush vented fuselage tank has resulted in fuel starvation. This was revised to a ram probe, solving the problem. Vent pressure measurements have confirmed that a ram type probe should be used on the fuselage tank. For new construction install a 1/4" aluminum tube inside the top of the fuselage tank and bring it out through the top and bend it 180 degrees to face into the breeze at least .6" from the top skin. For existing airplanes, it would work to install an aluminum tube into the fuel cap (see sketch), however there will then always be the danger that the cap may inadvertently be installed backwards, whereupon the fuselage tank may be rendered useless.

SKETCH OMITTED

PV FOAM AND WEIGHT CONTROL
The original PV core foam, type R45 dark blue, that we tested here at RAF, layed up absolutely perfectly without using slurry. Based on this series of tests, we called out no slurry on type R45 PV foam in Long-EZ plans. The production type R45 PV foam in most cases is representative of our test samples, however in a few cases larger cell foam is being delivered in the kits. This large cell foam is structurally excellent, and can be layed up without slurry with real acceptable physicals, however it is a lot easier to accomplish the layup if you slurry the type R45 PV foam. The glass wets out quicker and you get less air or dry looking areas. There is little or no difference structurally, but our test have shown a slightly lighter part if you use slurry. The best thing to do is conduct your own test as you build and decide for yourself which way works best for you.

In all cases your glassing time should not exceed 2 minutes per square foot per ply, i.e., front side of front seat bulkhead, is two plies, and should take no more than half hour. If you are working slower than this you are doing something wrong, and you will end up with poor work, heavy parts etc., due to epoxy gel. Above all, don't leave excess epoxy in a layup. If a squeegee can remove epoxy, do remove it. Use numerous squeegee passes to wet out as well as to remove excess. Remove the grams of excess epoxy from every layup, and your airplane will be many pounds lighter and stronger.

Do not add extra glass anywhere. One VariEze builder wanted his airplane "extra strong" so he added a ply here and there. His airplane

is over 100 lb. overweight and his strength for flight and landing loads is less.

Chase after grams, and the pounds will take care of themselves. Bill Lear once said he would kill his grandmother for a pound. While this measure is not recommended, it is possible if you are not diligent on weight control throughout your project you will be building a sluggish, single-place airplane.

REFERENCE LONG-EZ CHAPTER 14, STEP 13
At least a couple of you Long-EZ builders may have noticed by now that, due to the kink in the centersection spar it interferes with the aft seat bulkhead when you try to slide it into the fuselage. Do not remove the firewall to clear this. Using a coping saw, remove a triangular piece of the back seat bulkhead about 1" deep at the center and tapering to zero at the sides. After the spar's in place this piece is installed with wet micro and is structurally tied in by the tapes that lap onto the spar. For new construction do not permanently install the plywood firewall bulkhead in Chapter 6 or 7. Put the spar in from the back in Chapter 14, then install the plywood firewall bulkhead, lapping 1 ply BID around all edges.

CP25, Page 4

HOT WIRING
Important - do not substitute lighter tube than the 1/2" dia. steel tubes for the hot wire saw. The wall should be at least .049. The hot wire must be tight to operate without wire lag. Tighten till the stainless wire starts to yield (tone no longer increases when "strummed", as you tighten).

BUILDER HINTS
You can avoid cutting the bulkhead patterns from the plans if you over-lay the foam with normal typing carbon-paper then trace the patterns through the plans. This works great for hotwire templates too.

Long-EZ hints
Whenever BID tape is called out in the plans, this refers to a given width of BID cloth cut off the roll at 45 degrees to the selvage edge. This "tape" then works into a corner "variesily" as compared to 90 degree tape. Pre woven BID tape at 45 degrees is not available to purchase anywhere to our knowledge. It is ok to lap 1/2" where a long piece is required. Do not confuse these "tapes" with the spar cap material (3" wide unidirectional tape).

Long-EZ Fuel Tanks
CAUTION!! Be sure to align bulkhead's RB45 and RB23 parallel to the B.L. (fuselage CL), or your tank will not fit the wing.

When boring the 5/8" dia. holes in the centersection and wings, using the spotface tool, go slow!! Clear the spotface frequently and be sure not to get the layup too hot. Resharpen the tool if required.

Carving the inside of the fuselage bottom R45 PV foam can most easily be accomplished by using a very stiff wire brush, cup or cone shaped, in a drill and cut the foam away about 1/4" to 3/8" at a pass. Then

smooth it down with a high speed hand held disc sander (Metabo, Bosch, etc). Finish it with #40 grit sand paper in your fingers. Be careful not to gouge the foam in the corners with the edges of the sandpaper.

Carving the outside shape of the Long-EZ fuselage will be a lot easier if you rough the corners off with a large carpenters saw (careful not to cut too deep). Then use a body sander with a course sanding disk (or any highspeed power disc sander). Sand right into the bottom longeron till a max. of 0.4" of wood is visible. This gives you a rough shape. Now get a real coarse wood rasp (hardware store). This tool will remove foam with very little effort, and will enable you to arrive at a really pleasing shape. Finish with a 36 or 40 grit hard sanding block. This entire carving job can be done in 2 to 3 hours.

After carving the outside of the fuselage, just before laying up the outside skin, lay out the outline for the speed brake with a magic marker. Now stick strips of grey tape (furnace duck tape) in this area covering the entire speed brake area. Then proceed with the UND skin layup. When you cut out for the speed brake it will be much easier to separate the glass skin from the R45 PV foam. Unlike the urethane foam used for the VariEze fuselage, the R45 PV has tremendous peel strength retaining the glass skin.

BUILDER HINTS - VARIEZE ONLY
When laying up UND spar caps be sure to butt the cap material to the wing fitting and squeegee outboard. Do not trim the glass cap material at the fitting, "yaw" or slide the UND to butt to the wing fitting (keep fibers straight spanwise).

Addition to CP 24 page 11.
We omitted the W.L. and B.L. of the nylaflow tubes routing the pitch trim cable through the instrument panel. These should be at B.L. 9.5 (5/8" inboard of the left side) and top cable at W.L. 9.6", bottom cable at W.L. 8.3" (top of longeron in W.L. 23).

INSTALLATION OF LONG-EZ GEAR ON VARIEZE
Builder Report by Craig Gottschang.
Since the original VariEze main landing gear is no longer available, those of us building or retrofitting a VariEze must use the Long-EZ gear. Having just completed this installation on my Eze the following comments may be helpful to those building or retrofitting the Long-EZ gear:

The Long-EZ gear is both wider and fatter then the VariEze gear and consequently the aluminum extrusion attachments are spaced wider than the Eze. Rather than having two 1/8" extrusions sandwiching each gear attachment tab, two 1/4" extrusions are used on each fuselage side with a single 5/8" steel rod extending between them, upon which the gear tabs are mounted. The gear tabs themselves are beefed up considerably with BID layers locally on both sides while the wrap cloth is actually thinner using 18 layers of UND top and bottom.

The main gear comes from RAF with a 1/4" ridge all around, apparently from the molding process. This ridge must be sanded away flush and a power grinder is a necessity. In addition, 3" of each leg must be cut off for proper gear height on the Eze. The plans call for an 8 layer UND buildup, layered in crisscross fashion, to improve the torsional

strength of the main gear. I questioned the requirement for so much beefing up for use on the lighter VariEze but RAF informed me that the basic gear has little torsional strength in itself and must have the UND wrap whether used on the Long-EZ or the VariEze.

Having already installed the 1/8" extrusions on my Eze, my initial plan was to use them on the new gear. Unfortunately, they are too close together and would not allow a smooth "U" shape to the wrap around layers. I was concerned that this would cause an inherent weak spot in the attachment tabs. In addition, the old extrusions are not wide enough to accommodate the larger gear tabs. I found that the old extrusions could be removed easily by simply unbolting the popping them loose. It was not necessary to uncover the heads from the outside as they were held securely by micro. After removing the old extrusions I ground off most of the protruding bolts. The two forward most bolts on each side are common to the new extrusions and should be uncovered from the outside skin and removed. The new aft gear extrusion is aft of the old attachments, requiring the insert of some .7 x 1.0" wood pieces locally and then a BID buildup to support the new 1/4" extrusion.

Before installing the new extrusions, (retrofit only), determine which attachment holes may be drilled from the inside and go ahead and pre-drill these 1/4" holes in attach. Some of the holes may not be drilled from the inside due to seat back interference and are more easily located from the outside if not pre-drilled. When installing the attachments, bolt them together with the steel tube in between and position them in the airplane with clamps. Where able, drill the holes from the inside, temporarily bolt these, and then drill the rest from the outside. You may wish to remove the extrusions for final drilling through the aluminum. Once all holes are located and drilled, the extrusions are permanently installed with flox.

The actual mounting of the landing gear is easier than the old method and the plans are clear on this operation. The only change is to lengthen the aft gear tab (plywood jigging block) by .25". The tab needs to be longer than the Long-EZ due to the greater forward tilt of the main gear on the VariEze. The plans also call for a 5/8" diameter "spot facing tool" for use in construction of the gear tabs. This is a tool used frequently in the Long-EZ and sells for $29.95 from EZ distributors. Borrow one from a Long-EZ builder if you can.

The new gear installation requires an additional set of drawings from RAF at $7.50. The steel rods, with inserts are $9.90 each from Brock and 1/4" extrusions may also be available now. Other hardware is available from Wicks or Aircraft Spruce.

Although switching to the new gear initially seems like a lot of extra work, it is actually not that difficult and in fact easier than the old system. Above all, you end up with a landing gear that will withstand a crunch job landing now and then with complete confidence. From the looks of mine I think it could withstand a landing in a minefield! It is worth the effort. **SKETCH OF FORWARD EXTRUSION OMITTED**

LONG-EZ LYCOMING EXHAUST SYSTEM

The adjacent drawings show the system now being tested on N79RA. This system is very similar to the original one which we welded up ourselves, with the addition of a "ball" joint on each stack to take

care of vibration. It is working well so far, and looks like the way to go. This system is made and sold by Ken Brock, and can also be used on Lycoming powered VariEzes. Note: Lycoming flanges and tube sizes are shown. If you have a Continental engine, refer to Section IIA and build a similar exhaust system to exit the lower cowling just below the trailing edge at B.L. 19.5". A Continental version is not available from Ken Brock at this time.

(Drawings on page 7 and 8)

PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas, FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LONG-EZ PLANS CHANGES

LPC #5, MEO, Page 5-1
Spacing between dimension on fuselage sides is 10", aft dimension is 3".

LPC #6, MEO, Page 20-2
Add A,B,C, dimensions: A = 102.15"
B = 108.35"

C = 118.35"

LPC #7, MEO, Back cover of plans.
Wing root leading edge should be 113.9", not 113.4"

LPC #8, MEO, Page 19-8 Step 9.
Second line should read "form the 0.7" rib by removing foam with a rotary file".

LPC #9, MEO, Page 19-6, Step 6.
Third line down LWA7 should be LWA2.

LPC #10, MEO, Page 19-6.
Lower right paragraph, LWA7 should be LWA2.

LPC #11, MEO, Page 19-7.
Bottom right, 3 lines up, LWA7 should be LWA2.

LPC #12, MEO, Page 19-8.
Bottom left, 2 lines up, LWA8 should be LWA7.

LPC #13, MEO, Page 20-1, Step 1.
Third line down, Add page A3 and A14.

LPC #14, MEO, Page 2-2.
Airframe bolts AN3-11 should be AN3-11A

LPC #15, MEO, Page 2-1 Tools.
Change "2 pcs 16 x 48" to "One piece 1/16" or 1/8" thick x 24" x 48"

LPC #16, MEO, Page 10-2.
Clarification: Remove the word "centerline" two places, W.L. 19.4 is correct, but is not centered on the shear web.

LPC #17, MEO, Page 4-2.
Bottom right: Clarification: "both sides" means "left and right, on the forward face only"! The foam doubler goes on aft face, with no additional plies at this time. See Section A-A, B-B and C-C on page A3.

LPC #18, MEO, Page 3-3.
Jig table size omitted - add 3 ft x 11 ft.

LPC #19, MEO, Page A4.
Engine mount extrusions "Chapter 6" should be "Chapter 14", 2 places.

LPC #20, MEO, Page A5.
Clarification: The 15 ply BID pad for the aft gear attach angle should stop at W.L. 12.35 (Don't glass above 12.35)(Chap 5).

LPC #21, MEO, Page 2-4 Metal.
"3 ft of 1.8 x 1" x 1" should be "3 ft of 1/8" x 1" x 1" aluminum angle"

LPC #22, MEO, Page A-3 correction.
Hole for gear retract drive tube should be 1" to the right of CL.

LPC #23, MEO, Page 13-6.
NG 31 is called out of R45 dark blue foam, should be R100 1/4" red foam, see page 2-3. Also note on page 2-3 that F28 can easily be cut in one piece from the instrument panel foam sheet.

LPC #24, MEO, Back Cover
Nose gear CL is a W.L. -22 not -23.

LPC #25, DES, Page 4-3 and Page 2-2.
Aluminum can be substituted for the steel firewall, don't install fiberfrax now. Wait until after cowling installation. This allows you to wrap the fuselage skin around onto plywood and allows you to layup the 1 ply inside lip on the cowl lip. You will then have to remove things bolted to the firewall to install the fiberfrax and aluminum. Install fiberfrax with silicone rubber, not epoxy.

LPC #26, OPT.
To save work and weight substitute UND for BID on centersection spar as shown on page 4 of this newsletter.

LPC #27, DES.
For rough or grass fields and to relieve stress on nosegear components, install the spring assembly (page 8) in place of the NG 9/10A rod.

LPC #28, MEO, Page 14-2, Step 4.
Outboard LWA 1 (sketch on left center of page) 1.0" dimension should be to outside of CS 5 and 8, not inside. Change inside dimension to 0.75". Be sure to transition edges of all metal parts with flox.

VARIEZE PLANS CHANGES

DES, Sect IIA, Page 7
Sect IIC
Revise fuel vent system per this newsletter page.

DES, Section I, Page 22-5
Move canopy safety catch to F.S. 57.

DES, Sect I, Page 9-3
Alum can be substituted for the steel firewall if fiberfrax is used. Don't install asbestos or fiberfrax now. Wait until after cowling installation. This allows you to wrap the fuselage skin around onto plywood and allows you to layup the 1 ply inside lip on the cowl lip. You will then have to remove things bolted to the firewall to install the fiberfrax and alum. Install fiberfrax with silicone rubber, not epoxy.

LONG-EZ SPAR-CAP THICKNESS - CENTERSECTION SPAR AND WING
The number of plies of the UND tapes for the spar caps shown in the plans (Chapter 14 and 19) is based on each ply being .035 to .038 thick. We have found that some of the UND tape is of less bulk than expected, and is laying up only about .025 per ply. If this happens, the spar is weak and the depressions are not filled flush. Check your spar cap material by making a 5-ply layup. Cure then measure thickness. It should be 0.18 thick. If it is only 0.125 thick you must add the following plies to all your spar cap layups. All the additions can go on top of the plans shown caps.

Chapter 14, Step 7, Bottom Cap.
Add 1 Ply full span, plus 1 ply to B.L. +-45, plus 1 ply to B.L. +-30, plus 1 ply to B.L. +- 15.

Chapter 14, Step 7, Top Cap.
Add 1 ply full span, plus 1 ply to B.L. +-47, plus 1 ply to B.L. +-37, plus 1 ply to B.L. +-27, plus 1 ply to B.L. +-17, plus 1 ply to B.L. +-12.

Chapter 19, Step 5, Bottom Cap.
Add 1 ply B.L. 25 to B.L. 130, plus 1 ply B.L. 40 to B.L. 90.

Chapter 19, Step 7, Top Cap.
Add 1 ply B.L. 23 to B.L. 140, plus 1 ply B.L. 33 to B.L. 92, plus 1 ply B.L. 40 to B.L. 78.

CAUTION! - Use care in carving spar cap troughs, (Chapter 14, Step 5). Do not carve too deep!

ITEMS FOR SALE AT RAF - Pick up or Ship.

Long-EZ (VariEze) Main Gear	$277.95
Long-EZ (VariEze) Nose Gear	49.75
VariViggen Fiberglass Parts:	
VV Cowl - left or right half	$129.50
VV Nose Bowl	92.00
VV Tank Cover	63.00
VV Visor	68.00
VV Landing Light Dome F25	9.50

Canopies, Shipped FOB Dayton or Picked up at RAF
Long-EZ or VariEze Canopies.

Clear	$199.00
Green	229.00
Smoke	249.00
Bronze	249.00

Add 6% for California orders. Add $20.00 for overseas main gear orders. Main gear are shipped by Greyhound - please include telephone number with order. Main and nose gears and canopies are generally in stock for pickup at Mojave. Call ahead for availability of VariViggen parts.

BITS AND PIECES
Cutaway Prints of VariEze, printed on 80 lb paper, rolled in stout mailing tube $9.95 each or 3 $25.00. Suitable for framing. Also available folded in a 8 1/2" x 12" clasp envelope for $7.50.

C-85 Tapered Crankshaft, ground .010" under. Contact Richard Nelson (805) 544-5797.

CAN I BUILD A COMPOSITE AIRPLANE? WILL I ENJOY WORKING WITH GLASS & FOAM? IS MY WORKMANSHIP ADEQUATE TO BUILD AN AIRPLANE? WHAT ARE THE TECHNIQUES USED IN VARIEZE & QUICKIE CONSTRUCTION?

There is now available an introductory kit to answer these questions for you. The kit consists of a book and sample materials, or the book can be purchased separately. The book, "Moldless Composite Sandwich Homebuilt Aircraft Construction" consists of 26, 11x17 pages (equal to 52 pages) describing how the material is applied, education on the materials, tools required, inspection and repair methods. Sample materials include: foam (2 types), fiberglass (2 types), epoxy, microspheres, flox, peel ply, wire for hotwire saw, etc.

The book is $14.50, and is available from Aircraft Spruce, Wicks Aircraft Supply, and Rutan Aircraft. (Add state tax, if resident).

The kit (book and materials) is $45.00, plus postage, and is available from Aircraft Spruce and Wicks, not from Rutan Aircraft. (Add state tax, if resident).

LIST OF EZ'S THAT HAVE FLOWN
RAF maintains a list of completed EZ's so we can contact you direct in the event of a flight-safety related problem requiring an emergency directive. This list is also beneficial to access statistical items

relating to structural and system reliability. The list is, of course, kept in confidence. A print out of registration numbers is shown below. We believe there are about 100 flying VariEzes that are not on our current list. If you have an EZ flying please scan this list to find your number. If you are on the list please write RAF and tell us the date of first flight and the current total flight hours. If you are not on the list please write and supply: 1. Type (Long-EZ, VariEze, VariViggen).

2. Name of Owner.
3. Address.
4. Date of first flight.
5. Registration number (N-number).
6. Total hours.

Ray and Nova Cullen have moved.
New address is now: Rt 1, Box 213 #26
Baker, OR 97814
(503)523-5096

They are now offering plans for their survival kit plus the custom VariEze/Long-EZ seats for $8.00. They will also supply some of the more difficult to locate items of the survival kit. They are still interested in supplying any builder support that is requested even though they are now in a very rural area.

The canopy seal they are using on the side rails of the canopy is a 3M Adhesive Weather strip part #021200-01235 Cat #1235, Stock #93011. It is sold in a few stores there in Oregon but is still hard to find. Nova and Ray have tried almost everything on 22809 to gain rain protection and this stuff is the best! Note: Ray and Nova keep their airplane out a lot in a very wet climate.

VARIVIGGEN NEWS - By Mike Melvill

Here it is almost time to pack the Viggen and head for Oshkosh, where has the year gone? Hopefully this year we will have another Viggen to look at on the flight line. James Saunders of Miami, Florida, has got his Viggen N17VV, flying once again, and reports that he is very happy with his ship and has over 35 hours on it now with no problems. James' Viggen has the SP wings and a very pretty rainbow paint scheme. He also has a very complete, full IFR panel. The only change Jim recommends is to lengthen the nose gear strut by 1 1/2". He reports that this has substantially shortened his take-off roll. I have not tried this myself, so can not recommend a good way to do this. I will endeavor to obtain this information from Jim for the next CP.

N27MS has been to several airshows lately and now has 421 hours and 530 landings. The latest alternator is performing flawlessly (touch wood!!). My fuel gauge and oil pressure gauge (both Westach) are becoming erratic. I plan on replacing both with a new type that Aircraft Spruce is now stocking. Made by Rochester Gauge Co., they are bona fide aircraft instruments and look excellent. I will report on their performance in a future CP.

We have not heard from too many Viggen builders since CP24, but Bill Campbell is working on composite main wings, the rest of the aircraft is ready to paint. Gene de Reulle reports good progress on his Viggen, and sends the following builder hints:

"During the construction of every aircraft, there is a job that the builder dreads. On my Viggen I was particularly dreading the job of grooving the .2 x .3 capstrips for the ribs in the inboard wing. I realize that most builders do this by adjusting the blade height on their table saw but my table saw is old and not that accurate. Besides that, running a strip that small on a table saw is asking for short fingers if one makes a small slip. I think by accident I discovered a better way and I'd like to pass it on to other Viggen builders that may be coming to that stage.

I cut the .3 inch thick spruce (A/C Spruce Viggen kit) into .2 inch strips. Then taking my Dremel tool and Dremel router attachment with the smallest router bit they make, (I forget the number, but in the display case its the smallest) and clamping the spruce to a flat

surface and adjusting the router guide, I made a square notch the length of the strip.

The groove is so exact that its a beautiful fit on the 1/8" ribs. In fact, even on a curved surface, the capstrip can be held in place for glueing with only masking tape.

Starting at 9:00 am, I was able to cut; groove; fit; and glue all the capstrips for the top of the entire inboard wing by 1:00 pm. Now I will have to find something else to dread".

Arthur Schwartz came to Mojave for a check out in the Viggen in May, his report follows:

"I was beginning to see the light at the end of the wind tunnel and felt that I could best help myself with check ride in a Viggen before testing my own craft which should be ready in early August. I contacted Mike Melvill and arranged to arrive at Mojave airport in the afternoon of May 2nd. Finding the Rutan hangar made for no difficulty. Introduced myself to Sally and soon met Mike. Both, immediately gave me the feeling that I was an expected guest with most comfortable feelings. Within another few minutes I was looking at 27MS and filled with admiration and envy. I just don't think there's a higher compliment to be expressed. Before I could say or think much more I was seated in the rear seat, buckled-in, wearing a head-set and talking with Mike with a reliable intercom. For this trip I was going to follow Mike through. Mike invited me to taxi and I was quickly impressed about the ease of S turns with gentle pressure on the toe brakes. Mike encouraged me to go a bit faster and at about 20-25 mph, I'd judge, the air-rudders were quite effective. The large vertical fins do their job well. There was a very solid and substantial sensation to the taxi. At the end of the runway Mike went through the check-list and set the reflex at 8 degrees. The elevation at Mojave is about 2,900 feet plus an OAT of 85 degrees giving us a density altitude of about 5,000 ft. So, I was expecting a rather long ride down the runway. Mike advanced the throttle and we were rolling. I was likewise on the throttle and stick but without any input. I was just getting the "feel" of things. Mike suggested that I watch the canard as a reference point and get the sense when it starts to fly. It seemed to me that it doesn't begin to fly gradually as we're more accustomed, but sharply. One moment it is not flying and the next it is. We were climbing about 750-800 feet per minute and Mike was reducing the degrees of reflex to about 4 degrees. The vibration was smooth, the noise well behind us and with headsets things were really quiet. The rear cockpit has adequate instruments for flying, i.e. airspeed, tachometer, compass, and information about gear position. When we got to about 5,000" msl Mike made some stalls but, of course, only the canard. It was ever so gentle. Then he asked me to try my hand at flying. At this very moment, I knew that I had a very different airplane. Sensitivity with a gentleness. This might be thought of as a contradiction in terms, however I think not. I was immediately impressed with the high rate of roll and this was at speeds of about 140 mph. So, I'd say that a low time pilot might have a tendency to over control. But, this high rate of roll becomes at low speeds the ease of handling and touching-down exactly where the heart desires. The commercially built airplane that came to mind was the Mooney where the ailerons are also quite effective. Since the

afternoon was well upon us and the air was somewhat bumpy Mike suggested landing and to start early the next morning. I felt that the motion in turbulence was not all that unpleasant and I could have easily spent more time. I was just so impressed with the responsiveness of Viggen that I was not too bothered by anything short of something really major taking place. Came in downwind, throttle back, at some speed below 120 mph let the gear down, set reflex at 4 degrees. When we were at cruise the reflex was all the way aft or 0 degrees. At Mike's instruction I set up an attitude that gave me a speed of about 75 mph. Held the airspeed but having no sensation of a nose high condition. To stay lined up with the runway presented no difficulty. Wind was light. From the rear seat I began to have a problem sensing the height above the runway and took instruction from Mike in the front seat. At the moment, just before a touchdown the slightest bit of flare, just a little. The mains were down and directional control was easily maintained with air-rudders. At this time Mike reminded me of how the canard will stop flying. The very same way it starts - - - suddenly, and I should try to hold it off so the nose gear doesn't hit hard. I had a couple of good ones and a couple of not so good.

The next morning things were different. It was cool, quiet and I was sitting in the front seat. After the day before I was starting to feel like this airplane and I were made for one another. What else gave me that feeling was Mike Melvill as an instructor, he was there but also wasn't. He really permits you to be in charge and learn from what you do right and from what you do incorrectly. Today we were going to do the things that you must do before you take the airplane high in the air away from the runway and the earth. It's the thing that most pilots never do and it's controlling an airplane in that state between flying and not flying. We were to lift the nose wheel off while going down the runway and test pitch authority and aileron control (rocking the wings while riding on the mains). After going through the check-list I placed myself on the center line and know that I have about 10,000 feet of runway ahead. Applied power and got moving to about 50-55 mph, came back on the stick until the nose wheel lifted off and at the same time reducing the power ever so slightly. In this condition you can move the stick forward and back and watch the nose rise and fall demonstrating the pitch authority. The lateral movement of the stick (gingerly) will rock the wings. I did that up and down the runway for a considerable time. It builds confidence in feeling about handling, and the responsiveness of the Viggen is tested. Next Mike suggested I try a lift-off of nose and mains but to stay in ground effect. Reflex at 4 degrees, more power than for just nose wheel lift-off, until moving close to 60 mph plus, a lift off, test the pitch control and lateral movements of the wings and then ever so gradually reduce power. Especially not to be concerned that all the runway is gone and make the sad error in a pusher by chopping the power. If there's one place where pilots who don't have pusher experience, is being surprised when the nose-up attitude develops with reduced power, (abrupt reduction of power). But, generally in an airplane all changes should be done slowly and with gentleness. From this point it was into the air with making landings and take-offs. While I came to this experience with 400 hours, in my homebuilt Volmer Amphibian (pusher configuration) I regard and strongly urge anyone thinking about testing flying his newly built Viggen to visit with Mike and reward yourself with this most valuable experience.

A curious state of affairs develops between builder and airplane over the years of construction. The builder comes to regard the plane as a kind of extension of himself and endows the plane with some human features. Especially the one that the plane will take care of you, albeit without you having to do the flying. The reality is quite different you must be prepared to fly, the plane can't. There is a kind of old wives tale that goes through aviation circles to the effect that the builder should not test fly his own airplane. As far as I know the dynamics behind this remark has never been expressed and so I've taken this liberty to give a small insight into the relationship between builder and his creation."

This summer/fall will surely see a couple of new Viggens flying, Arthur Schwartz, Ken Guskott, Frank Stites all report being very close. See you at Oshkosh.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Where does it all go? Burt and Dick inspecting the various baggage and nose baggage areas in the Grand Champion "Pegasus" VariEze. Norm Ross and friend Glenne Campbell stopped by RAF recently on one of their many trips. Norm has flown the Grand Champ more than 300 hours since Oshkosh '79! During their stay Norm flew the Long-EZ and Mike, Dick and Burt flew Pegasus. We can now say first hand that this airplane performs and handles excellently. Even though it is well equipped, it is one of the lightest EZ's flying. Norm has the empty weight down to less than 600 lb. now, with alternator removed. Norm is the recognized expert in weight control. He fabricated intercylinder baffles by wetting out 1 ply BID with silicone rubber, then (after cure) mounting them with silicone - presto - a fatigue free baffle that is lighter than aluminum. Norm's CHT runs less than 350 degrees F on the O-200. It can be done, with good baffle workmanship.

This photo shows the extensive baffling on Steve Woods' O-200. An article on Steve's work will appear soon in Sport Aviation magazine. Also shown is the tufts on Steve's boat tail (photo by Steve from the back seat of the Long-EZ). The amount of turbulence is similar to the standard cowl. Whetted area is greater. The inlet itself is lower drag than standard.

New Brock exhaust installed on Long-EZ.

Burt----
I epoxied the polyurethane together and carved the fuselage as per your VariEze plans. Either your instructions were too vague or I misconscrewed them. The enclosed photo shows me carving away at FS42 just before I discovered my error. Can you offer a fix or should I fly it this way? You may answer in your newsletter because it might help others who have had this problem.

Jud Hansen

Omaha, NE 68134

Initial cowls out of the new metal tooling for VariEze and Long-EZ.

TESTS PROVE OLD FIBERGLASS AS GOOD AS NEW
Fiberglass composites were introduced 40 years ago, but only now have their service aging properties been tested. And the results are a revelation.

Real-life tests on fiberglass samples were carried out by two scientists at the Grumman Aerospace Corp., George Lubin and Peter Donohue. With a bit of scientific detection work, they tracked down fiberglass components from 11 to 19 years old that had flown on Grumman aircraft and that had been extensively tested prior to being put into service.

Before this effort, the only published data on aging of fiberglass composites were those based on accelerated testing performed in the laboratory, which is the standard tool in use for testing both fiberglass and other composites for in-service structural degradation.

According to Lubin, "hard work, luck, and the fact that Grumman wasn't quick to change fiberglass formulation" played a part in the unique opportunity to be the first to document actual before-and-after results on fiberglass components.

In their paper, "Real Life Aging Properties of Composites" --- selected best in its class at the 35th annual conference, Reinforced Plastics/Composites Institute, Society for the Plastics Industry--- presented last month, Lubin and Donohue detail the testing results on fiberglass components that flew aboard Grumman aircraft and were subject to extremes of climatic conditions and to combat. Without exception, all components tested showed virtually no degradation as long as they were properly protected by paint coatings.

Their conclusions dispel the myth that fiberglass degrades with age. More significantly, they throw into doubt the validity of accelerated laboratory aging, which invariably causes considerable degradation of samples tested---a result not supported by Lubin and Donohue's findings.

A reassessment of the criteria currently used for testing fiberglass composites is needed, the two scientists believe. They feel it is certain that current specifications based on such testing result in overdesigned and, therefore, overweight fiberglass structures. More realistic accelerated aging specifications would, they say, result in structures of fiberglass composites being lighter in weight. For aircraft, especially, this would permit significant savings.

The two also tested graphite composites, but owing to their relatively recent arrival on the composites scene, the results for these materials were not as conclusive as those for fiberglass.

ANCIENT AIRCRAFT PARTS PROVE DURABILITY OF FRP

Fiberglass composites don't degrade with age, provided they are protected by paint coatings, tests of 11 to 19 year-old aircraft components show. The tests also throw into doubt the validity of accelerated laboratory aging.

Boat-tail tested on VariEze N4EZ - Also installed is the new Great American Prop.

The RAF crew with the Long prototype. Left to right: Pat Storch, Burt Rutan, Dick Rutan, Sally and Mike Melvill, and Roger Houghton.

The Long-EZ prototype on grass. 500 x 5 tires are mounted, as well as the spring strut. The ride and handling is similar to most light-planes - very pleasant.

It seems the fastest Long-EZ builders are those that have built VariEzes. The adjacent fuselage is the first 1 1/2 weeks work by Herb Sanders. Other EZ-types of note are Ed Hamlin and Don Shupe. Ed and Don have a total of just under 1000 hours on their EZ's. Ed, Joanne, Don and Bernadette plan a round-the-world trip for a summer vacation when they get their Longs finished.

Pat and Sally after Pat's Long-EZ solo.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Mike and Dick at work on their Longs. Note tools for fuselage bottom carving and main gear attach hardware. The AN4-16A bolts require two washers for mounting these brackets. A shorter bolt should not be used, as it results in threads in the bracket.

25 EZ's, a VariViggen and a Defiant at Mojave! All the people are inside having lunch.

Sally with RAF's Long-EZ. She soloed N79RA last year. Sally and Mike are now working about 30 hours per week building their own Long. They plan to fly the new one to the Bahamas this Christmas for the Hospitality Club Fly-in.

LONG-EZ

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE
The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent

pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE

At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY

The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to 27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be

shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES
Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased

from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

Brief Long-EZ specifications/Performance
Engine Lycoming 0-235 108 hp.

Span	26.3ft
Area	94.1 sq. ft.
Empty Basic	710 lb.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 26. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 26. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 26. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 26. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 through 26.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

Saturday Demos - Every Saturday (except as shown below) RAF conducts a demo at our shop at the Mojave Airport.

We start the presentation/discussion at 10 am each Saturday with flight demos of our experimental aircraft at approximately noon (weather permitting). This will be done each Saturday except on the date listed below.

27 December 1980 Christmas weekend.

We will be closed from the 25th to the 28th December and also the 1st and 2nd January 1981.

Bring any of your parts for inspection. We are located near the west end of the flight line at the Mojave Airport about 2 hours drive north of Los Angeles on Highway 14. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to

keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

ITEMS FOR SALE AT RAF

Long-EZ/VariEze Main Gear	$277.95
Long-EZ/VariEze Nose Strut	49.75

VariViggen Fiberglass Parts:

VV Cowl - left or right half	$129.50
VV Nose Bowl	92.00
VV Tank Cover	63.00
VV Visor	68.00
VV Landing Light Dome F25	9.50

Long-EZ or VariEze canopies

Clear	$199.00
Green	229.00
Smoke	249.00
Bronze	249.00

Add 6% for California orders. Add $20.00 for overseas main gear and canopy orders. Main gear are shipped by Greyhound - freight collect. Please include telephone number with gear orders. We would like to have at least two weeks advance notice if you intend to come by and pick up either main gear, nose strut or canopies. Canopies are for pick up only at RAF, otherwise shipped FOB from Dayton, Ohio. Canopies - overseas orders---Freight on a canopy can be as high as $400, so if at all possible try to get with other builders to double up when ordering. Two or three can go for the same freight.

The Prototype Long-EZ prefabricated Fuel/Baggage Strakes
These will be installed on Mike's Long-EZ, to check the fit and develop installation drawings. These items should be available this winter. Bear in mind that these are large pieces and therefore are likely to be quite expensive. We will report on difficulty of installation and on building time saved in a report in the next newsletter.

NEW BROCK ITEMS
Ken Brock Manufacturing now stocks a new stick grip that fits VariEzes and Long-EZs. It is styled after the ski pole grip that nests the lower side of your palm, resulting in a comfortable, low-fatigue grip. Part no. LESG1. Ken also has in stock, the new square style 12 volt fuel pump. This pump can be substituted for the Bendix electric pump with a small weight savings and at less than half the cost. Part no. is EFB. We have recently finalized the engine mount design for the Lycoming dynafocal configuration. By the time you read this, Brock will have this item available.

Section IIC Lycoming Installation.
When we ran out of this section this fall, we decided to prepare a new edition, incorporating modifications and improvements for the Long-EZ. We have held up final layout and editing on this until Mike completes his Long-EZ dynafocal engine installation. Thus, the new edition will be thoroughly checked for accuracy, but will not be available until at least mid November. If you absolutely need one before that we can

xerox you a copy of the old edition, but we strongly recommend you wait for the latest.

THANKSGIVING SEMINAR - 29th November 1980
Rutan Aircraft and Quickie Aircraft Corp. will hold a joint workshop at Quickie Aircraft in Hangar 68 on Mojave Airport. Flight demonstrations of the Long-EZ, VariEze, VariViggen, Quickie and Q2 will be held between 10 am and 11 am. Lunch will be from 11 am to 12 noon. The workshop will be from 12 to 5 pm. There will be no catered lunch as such, but the airport cafe has been alerted and will have sandwiches available. We will have chairs, but it is possible that we may have more people than seats, so if at all possible, bring your own chair!

The seminar will cover methods of construction on Long-EZ, VariEze and Quickie aircraft. Anyone with parts they would like inspected, bring them along.

Due to an expected large crowd and in order to better prepare the airport cafe, please write and let us know if you intend coming, and the number of people in your party.

OSHKOSH 80
Sixty two VariEzes, both Long-EZs, a VariViggen and a Defiant at one flyin? The only place this can happen is Oshkosh. For the second year running, a VariEze won the Grand Champion Homebuilt Trophy. This year it was Fred Keller of Anchorage, Alaska. This is the third year he has flown his EZ to Oshkosh, round trip mileage 7000 miles! For a complete write up on Fred's airplane and on the Oshkosh convention, refer to the articles by Jack Cox in the October 1980 Sport Aviation magazine.

To help Fred celebrate, Burt and Pat flew the Defiant to Alaska after the Oshkosh show. We really enjoyed the Alaskan hospitality, and the beautiful scenery. Special thanks to Randy Doll, Norm Ross, Glenne Campbell, Peter Gerdtson, Fred and Sharon Keller and George and Ruby Pappas, for showing us what it is like to fly amphibians and floatplanes and how the bush pilots operate. Within the next year we may plan a Nome, Alaska to Puerto Rico non-stop distance record in a Long-EZ.

Our return trip was down the west coast, 13 flying hours from Anchorage to Mojave with an enjoyable overnight stay in Ketchikan, Alaska. The beautiful 17000 ft Mt. Logan with it's glaciers reaching to the sea is a sight we will not soon forget.

OSHKOSH 500 - The LBF Race
This years' race was well attended with the following entries:

- Four Formula-one Racers
- Two Long-EZ's
- Six VariEze's
- One Adventure
- One RV4
- One KR1
- One KR2
- One BD4

Two Mustang II's

This year, for the first time there was a separate $1500 prize for the best placing VariEze/Long-EZ. The following put up the money to sponsor the EZ class:

Aircraft Spruce and Specialty
Wicks Aircraft Supply
Ken Brock Manufacturing
Applied Plastics
Herb Sanders
Rutan Aircraft Factory

Steve Wood's VariEze N56EZ won the EZ class money plus $500 for placing third overall. Nat puffer won $200 for placing 5th overall. Refer to the October 1980 issue of Sport Aviation for detailed results. The LBF race is a good format for a comparison of airframe and engine efficiency. When reading the results, use care to note which airplanes flew two place since they are handicapped differently. To qualify for the VariEze prizes the VariEze must fly single place.

In order to compare efficiencies, we have taken the VariEze results and plotted miles per hour vs. miles per gallon. On this plot we have drawn a sea level theoretical curve assuming 0.5 specific fuel consumption, 1.4 sq. ft. f, 22 ft span, 0.9 span efficiency and 1050 lb gross weight. The data show that Nat Puffer's airframe/engine combination was the most efficient, having a very slight edge over Steve Woods. If Nat had opened her up and flown the race faster he probably would have beat Steve in fuel-corrected speed. Many had expected the watercooled Rotorway to be more fuel efficient than the aircooled engines. Race results show otherwise. It ran 8 mph slower than Woods, while burning 19% more fuel - both were running peak EGT mixtures. The reader is cautioned to not assume that all the differences are engine related, since there are often relatively large differences in airframes and pilot technique.

Only four of the two-place entries finished the race. Their relative efficiencies are shown in the second plot. The RAF Long-EZ ran at essentially the same efficiency as Kent Pacers exceptional Mustang II. Johnny Murphy's Long-EZ ran poorly mainly since he had to use rich mixture to prevent overtemping the oil (he has since solved his cooling problem).

GRAPHS OF OSHKOSH 500 RACE RESULTS OMITTED

LARGER ENGINES FOR LONG-EZ?
A number of builders have asked if it is feasible to install the 160hp Lycoming O-320 engine in a Long-EZ. At this time we must respond that this installation is definitely not approved. In order to approve this we would have to do a new structural analysis and possible beef up of a large portion of the airframe, install the engine, then conduct new tests to confirm structural adequacy and to develop the cooling, induction, vibration, exhaust, propeller matching, expansion of aerodynamic envelope, etc. Unless these tests and development are done it would not be known if it were feasible, much less recommended.

A larger engine will make the airplane tail heavy and lower the useful load. Higher horsepower would result in a small increase in speed and

a large increase in climb. However, the Long-EZ's ceiling of over 19000 ft at gross and demonstrated 27000 ft at light weights, makes it the last light plane that needs better climb! Lycoming engines have their best fuel efficiency at about 70% power. If an O-320 were throttled down to 51% power, to cruise at the same cruise speed as the O-235, it would burn more fuel than the O-235. The calculated comparison below shows that the O-320 saves only 18 minutes on a 500-nm trip, but costs $9.11 more in fuel. This is over $30 cost per hour of saved trip time.

	115hp O-235	160hp O-320
75% power cruise	161 kt	179 kt
75% power fuel flow	6.7 gph	9.32 gph
Nautical mi/gal @75%	24	19.2
Nautical mi/gal @127kt	37.3	36
Range @ 75% power (45 min reserve)	1150 nm	920 nm
Flight time-500nm trip	3 hr 6min	2 hr 48 min
Fuel cost-500nm trip	$36.46	$45.57

LONG-EZ HIGH DENSITY FOAM SUBSTITUTES

Due to excessive cost increases, the dark red, 0.2" R250 PV core foam is no longer being used in Long-EZ kits. For a while this summer and fall, 3/16" thick plywood was supplied in its place, We have recently approved a high density urethane/polyester foam (white in color, 18lb/cubic ft density) for this use also. If you receive the white foam it will be in four pieces, 12" x 48" 0.2" thick. This requires a micro joint for the instrument panel and F22. This joint need not be a separate cure, it can cure with the first skin.

Regardless of whether you are using the red or white foam or plywood, do not change any of the layups of fiberglass or any of the core carving shown on page 13-5 of plans.

Due to excessive costs of the aircraft grade of the R45 dark blue PV core foam, marine grade is being substituted for two of the eight pieces of 0.35" thick R45. The marine grade is identified by a slightly different thickness and an occasional void. Use the marine for the consoles and the aircraft grade for the tank skins. (see page 2-3 of plans).

Also, due to excessive cost increase, the 0.8" and 1.6" thick pieces of R45 are now being supplied in marine grade. The marine grade is available 32" wide rather than the 24" wide as shown on page 2-3. Even though you are getting some excess foam you are paying only half to two-thirds the price of the previous aircraft grade.

Marine grade and aircraft grade PV foam are similar in formula and structural characteristics. The differences are in the occasional voids and thickness tolerance. Fill any small voids with dry micro. Fill voids larger than 1/2" dia. with a foam chip and wet micro.

MIKE AND DICK'S LONG-EZ's By Mike Melvill

Progress has been good since CP #25. All major structural parts are complete, wings, winglets (upper and lower), centersections, fuselages,

canards, elevators, mains and nose gears. Dick plans on completing his in the same building we rented and I have transported mine to our home in Tehachapi, where Sally and I have been working like mad in our two car garage.

At this point our Long-EZ (N26MS November two six, Mike Sally) is on its gear, the canopy is complete and mounted, the engine is mounted. The canard is mounted, without the fairing block. The wings have been mounted and drilled into the centersection, which is hard mounted into the fuselage. The speed brake is installed and operational, pitch trim, roll trim and control sticks are installed. Upper and lower winglets are mounted on the wings, as are the ailerons.

Still left to do, mount the wing strakes (fuel/baggage areas) which will be the prefab parts (see page 1). Fit and install the cowling, install and hook up all instruments, throttle quadrant, and complete all plumbing and wiring. Then of course it is finishing time, lots of dry micro, featherfill, primer and paint.

Sally and I have been trying very hard to get our Long-EZ ready for the Hospitality Club Bahama's trip this Christmas. At this time I am not certain we will make it. To a large extent it now depends on being able to get all the little parts it will take to finalize the whole thing, we will keep on going as hard as we can and it will not be for lack of trying if we don't make it.

During the course of our building we have weighed virtually all the parts and kept an accurate record of man-hours we have spent building. Here is a list of weights and hours spent on the parts. Use this as a guide to judge if you are too heavy, too light or spending far too much time on a part:

Front seat bulkhead	2 lbs. 14 ozs.
Back seat bulkhead	1 lb. 7 ozs.
F28 bulkhead	3 ozs.
F22 bulkhead	1 lb. 7 ozs.
Instrument panel	2 lbs. 2 ozs.
Fuselage sides (with gear attach layup and angles and bolts)	10 lbs. per side
Fuselage, assembled with bottom on and carved outside, but not skinned	41 lbs.
Skinned fuselage, with roll over structure and speed brake (from F22 to firewall)	59 lbs.
Speed brake	2 lbs. 2 ozs.
Main gear strut with 8 ply UND torsional layup	24 lbs. 14 ozs.
Main gear with attach tabs complete	27 lbs.
Centersection spar	29 lbs. 5 ozs.
Wing, skinned top and bottom, no root ribs, ailerons cut out	46 lbs.
Wing, with root rib layups, and aileron trailing edge spar complete (no aileron)	46 lbs. 8 ozs.
Aileron with mass balance, hinges, torque tube and universal	5 lbs. 2 ozs.
Wing, complete to end of Chapter 19, with	

level reference board bondo'd on, ailerons, hinges, controls, etc.	51 lbs. 8 ozs.
Upper winglet with R.S.T. antenna, coaxial cable and BNC connector, ready to install on wing	6 lbs.
Lower winglet	1 lb. 3 ozs.
Canard no hardware, no elevators	17 lbs.
Left elevator, no hinges, no counter-weights	2 lbs. 2 ozs.
Right elevator, no hinges, no counter-weights	1 lb. 13 ozs.
Left elevator, ready to finish	3 lbs. 8 ozs.
Right elevator, ready to finish	3 lbs. 4 ozs.
Canopy complete ready to finish	16 lbs.
Fuselage, complete with centersection (includes side consoles) brake cylinders, main and nose gear (and fore and aft canopy frame) (500x5 tires on main gear) no wingstrakes, no canard, no canopy, no engine mount	183 lbs.
Wing, complete with upper and lower winglet, rudder mounted and hinged, ready to finish and bolt to mounted centersection spar	64 lbs.
Dynafocal engine mount	5 lbs. 3 ozs.

BUILDING TIMES IN MAN HOURS (MH)
Note: These are not just layup times. These are total hours worked for all people, including shop cleanup.

Fuselage, assembled with nose, nose gear, main gear, and roll over structure	86 mh
Main Gear (complete, no axles)	9 mh
Canard	38 mh
Elevators	8 mh (2 pcs)
Centersection	62 mh
Both Wings	97 mh (2 pcs)
Upper winglets	11 mh (2 pcs)
Lower winglets	6 mh (2 pcs)
Wing root layups, aileron cut out and trailing edge spar layups (2 wings)	15 mh
Ailerons, complete, hinged and operational in the wings with controls (2 wings)	32 mh
Canopy complete	36 mh
Wings, jigged to centersection and drilled in	6 mh
Upper winglet, jigged to wing, and all layups complete plus lower winglet, jigged and layed up	23 mh (per wing)
Rudder layout, cutout, layup, mount hinge and bracket, string cable	7 1/2 mh
Total Man Hours to date	458 mh

This is where I am at this time and we will continue to report progress, weights and times in future CPs.

TULLAHOMA 80 by Dick Rutan
This was our first time we had been to this event and thoroughly enjoyed it. Good weather, nice crowds and a lot of fun flying. The side trips to the "Grand-Ole-Opera" and the Jack Daniels distillery were interesting. I flew the Long-EZ each day in the airshow demonstrating it's maneuverability by doing some very basic aerobatics both with and without power.

The event was well attended by VariEzes and all the Long-EZs in the world were in attendance. Johnny Murphy flew his Long-EZ non-stop from Florida. Friday night the EZ crowd got together at the VFW club for dinner. I took the opportunity to give special recognition to some very nice flying machines. I selected John Benjamin N40JB VariEze as the overall winner with Steve Darlington N36SD and Robert Vaughan N66EZ so close behind they also received awards. "Good job guys, it makes us proud to see such fine machines".

The significant part of my trip was the demonstration of the Long-EZ, long range cruise efficiency by flying from Mojave, CA to Tullahoma TN non-stop arriving with fuel to hold almost two hours. Myself and my friend Jeana Farrar with baggage for two weeks flew the 1600 nm (1860 statute miles) in 10 hours 46 minutes non-stop, for an average speed 148.7kt (171 mph). This included a detour to see the Grand Canyon at dawn. The total flying time was 11 hours 6 minutes including holding an arrival airshow demonstration. Total fuel burn was 55 gallons for 4.74 gph. Fuel burn for the leg not counting holding was 53 gallons for 34.7 sm per gallon. Not bad for two people at over 175 mph true airspeed. In August, the non-stop flight to Oshkosh from San Francisco was virtually the same distance and speed as this one. We are very pleased with the data on both of these long flights because it was just slightly better than what is stated in the Owners Manual. Both flights were blessed with good smooth weather and a 3-4 kt average tail wind. At over 12000 ft cruise altitude, we were using only about 58% power. The Lycoming O-235 (at 1500 hours total time) ran smooth with very low oil burn.

On our return trip we stopped off at Ray Field, a little 2000' grass strip just south of Mobile Alabama, to attend a local EAA chapter meeting. Even with trees at both ends the Long-EZ operated out of the grass strip with no problem. I want to thank Rick and Kully Thompson and all the chapter members for replacing our burned-out landing light, and bedding us and the Long-EZ down for the night.

It is very interesting to note that Mojave to Tullahoma via jet airliner requires a 2 hour drive to Los Angeles, a 7.1 hour airline flight (including one stop) to Nashville Tennessee, a half hour baggage pick up and another one and a half hour drive.

MOJAVE TO TULLAHOMA - TWO PEOPLE, ONE WAY

	AIRLINES & CAR	LONG-EZ

TOTAL TIME	11.1 hours	10.8 hours
COST-AIRLINES	$580.00	-
COST-CAR	40.00	-
COST-FUEL AND OIL	-	$88.00
COST-DEPR. HANGER, OVERHAUL, INS	-	$90.00
TOTAL COST	$620.00	$178.00

It may surprise many to find that you can go 3/4 the way across the country faster than airlines and at less than 30% of the cost!

FROM THE BUILDERS/OWNERS
This section contains miscellaneous information received from the homebuilders that may be of interest to others:

FROM LAURENT MORELLE, FRANCE - "First flight 10 July 1980 for F-PYHT and no problem. It is a wonderful machine, I won Grand Champion cup at Brienne Le Chateau show and VariEze G-LASS (Don Foreman, England) won best foreign aircraft. Four other EZ's are flying in France. Mr. Lesschaeve reports the 5 EZ's were at the Brienne Le Chateau including Rudi Kurth (Switerland) and Mr. Ghimbal and Briguet of France. Our development of the nose gear shock strut (CP #25) was preceded by Mr. Bruno Ghimbal who uses a polyurethane damper on his VariEze nosegear. He reports it rides "like a Citroen CX!".

FROM DR. JOHN STEICHEN - "I would recommend the shock strut for all VariEzes. I recently removed the bolt from NG10 and found it bent with no memory of any pot holes".

FROM HARRY JOBES, MICHIGAN - "As a builder of both the VariEze and the Long-EZ, I have had the opportunity to work with both sets of plans. The VariEze plans and instructions are great... but those for the Long-EZ are an order of magnitude better.

Even though, in some areas, the Long-EZ is more sophisticated than its predecessor, the plans are easier to follow. Drawings are more numerous and crisper. Added cross sectional views are a big help. The designation of the layups is a thoughtful feature. The addition of bills of material by chapter and a foam cutting schedule are cost and time savers.

Keep up the good work! I am eagerly anticipating getting my Long-EZ in the air in 1981.

FROM RAY RICHARDS, TOLEDO, OHIO - "After 150 flight hours (VariEze) I disassembled the carb heat muff and found the carbon steel door spring broken into a dozen pieces. To replace, I wound 0.40 stainless wire into a spring on a lathe mandrel. Works great... other than that all is fine and N48EZ behaved faithfully."
Has anyone else had carb heat spring deterioration? Do check for this, it may be possible to ingest a piece into the engine.

FROM IVAN SHAW, ENGLAND - "I use modeling clay to hold jigs temporarily before applying the Bondo, real helpful and easier than playing about with shims. I bettered the wing layup times by using two 2-inch brushes, it doubled efficiency. I'm a drummer and can get 16 stipples

a second! While this works well for a professional drummer, we at RAF still recommend minimum use of brushes. By pouring on epoxy and spending most of the time with many light passes with the rubber squeegee, most people will do fast, accurate, quality layups.

FROM MABEL COHA, SAN DIEGO, CA - She and husband Al recently made a VariEze trip from San Diego to Alaska and back. "On July 19, 1980, Al and I departed from Montgomery Field, San Diego, Ca. in VariEze N2CR. Flight time to Sacramento, Ca. was 3+20. In Sacramento we visited Earl and Barbara Wilson. Barbara designed the VariEze Hospitality Club patch.

Flight time for the second leg to Victoria B.C., past Mt. St. Helens, was 4+41. After clearing customs we renewed acquaintances with Norm Ross and Glenne Campbell, after their visit to San Diego several weeks earlier.

The third leg from Victoria to Fort St. John was flown under overcast to broken clouds with scattered light rain showers. The flight time for this leg was 3+14. We refueled and departed for Whitehorse, Yukon with an ETA of four fours and five minutes and weather forecast of 3,500 foot overcast with light rain showers. Six miles west of Ft. Nelson the clouds merged into the trees. With 5,000 foot peaks ahead, we did a 180 and landed at Ft. Nelson. The flight time for this leg was 1+32.

After two days at Ft. Nelson, B.C. during which time we enjoyed meeting many friendly, curious, interested Canadians, the cloud base lifted to 5,000 feet. We departed for Whitehorse with the usual light rain showers in the mountains. By flying through the saddles, we were able to maintain VFR and arrived at Whitehorse after 3+11 enroute.

The 80 octane fuel truck was broken at Whitehorse so we had to round up some Jerry cans. We departed for Fairbanks, flight time for this leg was 3+30. After clearing U.S. customs and talking to the usual friendly group of people, we parked N2CR in the transient parking area and had dinner with a friend from San Diego who is now working with the Fairbanks FAA office.

After visiting the points of interest at Fairbanks and waiting for the weather to clear, we departed for Anchorage VFR below the overcast again. We spent several days in Anchorage with friends and attempted to attend a fly-in at Soldotna with Fred and Sharon Keller but were turned back by bad weather along the route. We departed for the

---

return trip to San Diego in a moderate rain and lowering ceiling getting through Chickaloon Pass before it became closed by weather. We passed through some of the most spectacular scenery in the Wrangell Mountains, a 'short-cut' between Gulkana and Burwash. We cleared customs at Whitehorse after a flight of 3+41 and fueled for Ft. St. Johns.

Again the weather forecast promised scattered to broken clouds and light to moderate rain showers for the leg to Ft. St. John. We were

able to maintain VFR once again and arrived after a flight of 3+54. After fueling for the leg to Victoria we were offered a ride into town, where we ate supper.

That night was the first time blue sky was overhead so we slept on the grass in back of N2CR. The leg to Victoria was flown in 3+43. On the way back to San Diego, we visited Orcas Island, (don't recommend stopping there unless they sweep the stones from the runway), Tillamook, Oregon, Sacramento and Watsonville.
Flying time for the trip was forty-five hours, fuel consumption 220 U.S. gallons, statue miles 7,200.

The scenery was spectacular with gorgeous snow covered mountains, glaciers, braided rivers, lakes, green plateaus, and rocky peaks. Quick changes can occur in the weather in this area at any time of the year. However, June and the first two weeks of July are apt to have the best weather conditions.

We found everyone who saw the VariEze showed much interest in the plane and now feel it should be named "Ice Breaker". It certainly has increased our circle of friends".

The photo elsewhere in this newsletter shows the equipment taken on the trip. Mable carried much of it on her lap! We wonder why someone named Al Coha wouldn't build an Aluminum airplane, or, what would you expect from Mr. E. Poxy!

FROM DAN LUNDBERG, HOUSE SPRINGS, MO - "I will be installing the VariEze rudder cable shortly. One of your newsletters stated that your trim can be eliminated by filling in behind the left rudder after the correct position is determined. Can I eliminate the yaw trim and parking brake? My plan is to ground adjust trim at rudder during initial flight tests and I see no need for the parking brake when parked nose down".

Answer - Yes, Dan, this is the currently recommended procedure for VariEze (CP#24 page 5) and is used on Long-EZ. You will find this better and simpler than the original VariEze trim.

FROM ED ROCKWELL - "I've decided to sell my VariEze, can you advertise it in the newsletter?"

Answer - Due to the inferred approval of airplanes that we do not have control over their quality control and workmanship, we cannot do this. It presents a possibility of liability on our part if it were defective. The builder of a homebuilt should seriously consider the liability aspects before selling his aircraft. Since he is an aircraft manufacturer todays American legal system may charge him for strict liability in tort. What this means is, if the airplane he builds injures someone he may be held liable even if he is not proven to be negligent! It's surprising what a lawyer may dream up if the airplane you built should ever crash. Even though you are not negligent in any way it could cost you more that the airplanes worth just to defend yourself. The following is a true story: An individual conducted all the flight tests of a new homebuilt in a competent and professional manner. He then put it up for sale. A buyer arrived and the seller conducted a full checkout. The buyer nearly crashed on his first

flight due to low pilot proficiency and low threshold of panic. The seller worked with him until his proficiency improved to the point where he was more comfortable, but cautioned him to not carry passengers and to fly in a limited envelope until he had a great deal more experience. The buyer left with the airplane and as soon as he arrived at his destination he took off with a passenger and with the cg out of limits. He crashed, killing both occupants. Now nearly two years later, the seller is being sued for ten million dollars. Because of the present ridiculous legal liability situation we at RAF would never sell any of our experimental aircraft. Both the VariViggen prototype N27VV and the VariEze prototype N7EZ were donated to the EAA museum.

FROM BYRON McKEAN - "I have the Goodyear 6-ply 3.40x5 tires and have ruined 3 inner tubes at the joining of the valve stem to the tube. I enlarged the hole and rounded the edges but it still went flat after 15 landings. Tire repair stations say the rim is too wide for this tire". Ben Duarte machined his wheels (and modified axles) to narrow them to reduce sidewall flexing, as he has had sidewall breakdown with his 6-plies. We at RAF believe the primary cause of both stem failure and sidewall failure is under-inflation. Under-inflation is almost always the cause of stem problems. When we introduced the 6-ply tires in CP #24 (page 7) we recommended a pressure of 80 psi. These tires are rated for pressure up to 95 psi. We ran them at 110 psi for the world record flight (gross weight was 1920 lbs.). We got over 180 landings on the first set and second set of 6-ply tires. We have run them too low (60 psi)for much of their service. We experienced sidewall breakdown in the form of blisters, near the end of tread wear, but never a flat. Because of the reported incidence of sidewall breakdown be sure to carefully inspect tires on your preflight inspections. (last pages of owners manual). If you have had or do have a breakdown or a flat, report it to us, indicating the service life and pressure history. We will access this data to determine if a wheel modification or change in tire specification is to be recommended.

GEHRES AND WOOD'S NACA INLET - TESTED ON VARIEZE N4EZ
Due to the interest many of you have expressed in the flush scoop we decided to evaluate it ourselves. We got the plans from Tim and Steve. They are oriented to installing the inlet on an already completed airplane, but may be used on a new construction project. First, we drained all fuel and oil and removed both batteries, removed the wings, and the canopy. Then we flipped the fuselage over, sat it on two saw horses and weighting the nose to keep it stable. Following the plans pretty close, we sanded the bottom, built cardboard dams, poured 2 part "pour-in-place", urethane foam, carved it to shape, cut down the existing bottom cowl and used blocks of urethane, as well as "pour-in-place" to build it up to the new shape. After it was carved to our satisfaction, it was glassed, filled and painted. The entire operation was accomplished in about 35 man-hours.
TESTING - Before installing the Gehres/Wood mod we carefully conducted baseline tests of ground cooling, climb cooling, cruise cooling and Vh (max speed with best power mixture at several altitudes). We repeated these tests after installing the engine baffling, then again after installing the flush inlet. Two CHT gages and four probes were used. Based on the Gehres/Wood testing, we had expected a large improvement in cooling due to the baffles and some loss of this improvement due to the flush inlet. The Gehres/Wood test results also agree with logic.

However, our test with N4EZ showed no cooling improvement with the baffle modification. A slight reduction in CHT was observed after we curled up the edges of the baffle pieces as shown in CP #22, page 4. Also, we obtained a definite improvement (30 to 35 degrees F) in cooling (CHT) when we installed the flush inlet. We contacted the other two VariEze owners known to be using the flush inlet (Johnny Murphy's Long-EZ and Ken Forrests' VariEze) and they both report an improvement in cooling. The reason for this is unknown, since theory and NACA test show that flush inlets do not have as good pressure recovery as ram scoops.

Our performance test were carefully run to accurately measure the speed change due only to the flush scoop. Full-throttle speed increased an average of 2 1/2 to 3 knots at density altitudes of from 4,000 ft. to 12,000 ft. Ken Forrest reported no speed change, but it's possible his test were not as accurately run. Johnny Murphy reported a larger speed increase, but he made other improvements at the same time.

To summarize: You can pick up a little speed (approx. 3kt.) and your engine will probably run a little cooler in level flight with the modification. A lot of people like the look of the airplane better with the "flush" NACA inlet (we call it the "female EZ").
Plans for the installation of new baffles and a NACA inlet for a VariEze or Long-EZ, are available for $20.00 from:

Wood and Gehres Inc.
105 Appleblossom Court,
Orlando, FL 32807

The plans are well done and easy to follow. They require you to discard the normal cowl-inlet and patch into your existing lower cowling. If there is sufficient interest in the NACA inlet we may consider investing in tooling to produce a new bottom cowl (or forward part of a bottom cowl) and the inlet (two molded parts that will bond to fuselage). If you would like us to see if these parts are available, please write in to RAF.

PROPELLERS
In CP #25 we announced the Great American Propeller Company (GAPC) as a recommended propeller manufacturer. Their 56x68 prop was one of the best we have tested on the Continental 0-200 VariEze.

We have just completed an evaluation of their 58x65 prop on the Lycoming 0-235 powered Long-EZ. The prop gives excellent performance and meets or just slightly exceeds the speeds listed in the owners manual. We are happy to recommend this prop to any Lycoming 0-235 powered Long-EZ flyer. The following is a current list of recommended propeller manufacturers:

Larry Weishaar
1924 No. 6th
Springfield, IL. 62702
(217)544-6086

EZCALC ELECTRONIC INSTRUMENT UP DATE
IN CP #24, page 7, we talked about an electronic unit that would give instantaneous fuel flow and trip average. Additional displays: Total fuel used/remaining fuel/distance/time to arrival and also to dry tanks. (Pilots in-puts ground speeds). Battery voltage, OAT, CHT, RPM, EGT, fuel low warning, clock, local, zulu time and approach timer. This all in a 3"x6" vertical oriented box. The developmental program is still in work, but delayed. We are currently expecting deliveries in February 1981. We should have an update in CP #27. Note: Long-EZ or VariViggen only. Installation requires fuel pressure, so this cannot be used on a gravity-feed VariEze.

PLANS CHANGES
We at RAF, of course, cannot enforce a mandatory change, as the FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas, the FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft in proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

CATEGORY	DEFINITION
MAN-GRD	MANDATORY, GROUND THE AIRCRAFT. DO NOT FLY UNTIL THE CHANGE HAS BEEN ACCOMPLISHED.
MAN-XXHR	MANDATORY, ACCOMPLISH THE CHANGE AT NEXT CONVENIENT MAINTENANCE INTERVAL OR WITHIN XX FLIGHT HOURS, WHICHEVER COMES FIRST.
DES	DESIRED - STRONGLY RECOMMENDED BUT NOT REQUIRING GROUNDING OF THE AIRCRAFT.
OPT	OPTIONAL - DOES NOT EFFECT FLIGHT SAFETY.
OBS	OBSOLETED BY A LATER CHANGE

MEO MINOR ERROR OR OMISSION.

LONG-EZ PLANS CHANGES

LPC #29, MEO, page 16-3.
CS119 should be 4.1" not 3.1"

LPC #30,MEO, page 10-3.
Upper right drawing #3 holes should be 1/4".

LPC #31, MEO, page 19-5.
Lower left paragraph, 3 plies should be 2 plies.

LPC #32, MEO, page 19-3.
Last paragraph, third sentence between "at" and "12" add "the correct place at the wing top. Hot wire "0" to".

LPC #33, MEO, page 11-2.
Lower left side, 3 lines up - should be 2 strips, not 3 strips.

LPC #34, MEO, page 2-1.
LMGA is used in Chapter 5 not Chapter 9.

LPC #35, MEO, page 9-1.
Landing brake paragraph - after the word "installation" add the words "and other important landing brake details".

LPC #36, MEO, page 19-15, page 19-16.
Clarification: CS127 can be made from the drawings on these two pages. Use .032" 2024T3 aluminum.

LPC #37, MEO, page 8-1.
Sides of roll over structure should be 13" not 12.7".

LPC #38, MEO, page 10-3.
Two places, cut 12 pcs. UND should be, cut 6 pcs. UND.

LPC #39, MEO, page 26-1.
"VariEze canopy (Chapter 22)" should be "Long-EZ canopy (Chapter 10)".

LPC #40, MEO, page 16-3.
The AN 315-3 jamb nut shown is not supplied in the bill of materials. It is satisfactory to substitute a MS21042-3 nut. Run a 10-32 tap through the MS nut before installation.

LPC #41, MAN GRD, page 33, Owners Manual.
After "70 to 80 psi" add "75 to 85 psi for 6-ply tires".

VARIEZE PLANS CHANGES
MAN, 100 HR, Sect. IV, pg 39.
Wing Attach Bolts - two builders have found corrosion in the wing attach bolts. Add the following to your owners manual: "Remove and inspect your wing attach bolts for possible corrosion annually or each 100 hours. Spray LPS #3 on the bolts and taper cones before reinstalling them, this will give excellent corrosion protection".

DES, Section I, pg 6-5
Add the additional information for attach fitting layups shown on page of this newsletter, CP 26.

MAN-GRD, Sect IV, page 33
After 55 to 65 psi add "(75 to 80 for 6-ply tires)"

VariEze Builder Hints

VariEze wing attach fitting layups, centersection and wings. Builders continue to have difficulty in achieving the proper layup thicknesses. The BID pads (8 places) must be laid up, weighted and cured per CP 15, page 6 or per Chapter 26 (second edition plans). For the number of plies of BID in each pad, use the table below, not the plans.

Now, after the BID pads are cured but before laying up shearwebs, spar caps or skins, measure the "X" dimension (top of BID pad to top of WA3 or WA5) and compare it to the table below . "X" must be at least the dimension shown, if not, sand the BID pads down before continuing. This step should eliminate buildups too thick to fit between the metal plates.

	# Plies in BID Pad	Minimum Dimension "X"
Wing Top	11	0.196"
Wing Bottom	14	0.151"
C/S Top	16	0.160"
C/S Bottom	19	0.124"

SKETCHES OMITTED

CP26, Page 6

LONG-EZ BUILDER HINTS
Wing jig Templates - Clarification - after gluing the 'A' drawing together, connect the W.L.'s with a straight edge. This will make it a lot easier to get things straight, and will be a check that the drawings don't warp when glued down. When Dick and Mike built their Long-EZ wings, the jigs fit the foam cores well except at the leading edges, where a gap of 0.1" and 0.4" was apparent between jigs and foam cores. A few builders have found this as well, and a few have reported that their's fitted tight. The jigs are sized to be a bit loose to avoid interference with the foam core and possibly there is some paper stretch or shrinkage during gluing. If you have a gap, it is not a problem. Go ahead and align the foam cores using the trailing edge as a reference, (butt core T.E. to jigs) and center the leading edges of the foam cores in the jigs, accepting the gap as shown.

SKETCH OMITTED

Wing Spar Caps - We have found a good way to clamp the spar caps during cure to get minimal waviness and to force them down level with the wing cores. See the accompanying sketch. Select some hot wire cuts of styrofoam (left over from wing core cutting) about 1" to 1 1/2" thick

and cut them 4" wide. These should be covered on one side with grey duct tape for a release, and you should cut and fit them end to end to go the length of the spar cap. Get these prepared before doing the cap layup. Now layup the cap normally, squeegee it out properly, then carefully place the foam pieces (with duct tape down) on top of the wet cap. Weight the foam down evenly with lead shot bags, milk jugs full of sand, salt bags or whatever. This will pack the cap layup down evenly and result in less sanding before the skin layup.

Canopy - page 18-2. Do not compromise the "A" dimensions, this 13 1/2" is required for good forward visibility. If it is desirable to lower the aft end of the canopy to better fair it into the cowling, or to meet the "B" dimension, it is structurally OK to remove the flange from the plexiglass aft of the roll over structure.

SKETCH OMITTED

When you get your canopy, do check a couple of dimensions: measure from the point of the plexiglass nose, aft 27". Now squeeze the sides in at the 27" point, till it measures 18.5", hold a straight edge across at this point, an measure up to the inside top of the canopy. For it to fit a Long-EZ satisfactorily this dimension should be from 11.25" to 12.75". If it is less than 11.25" it would reduce forward visibility by forcing the pilots head too low.

WING ATTACHMENT - Follow the instructions on page 19-18, step 1 except drill the 1/4" holes through the forward face and the aft face of the centersection spar. Now follow through step 2 and use two sawhorses/boxes per wing, with blocks of foam left over from the wing to bring the wings up close to the height of the centersection spar. Now cut 4 foam wedges 7" wide, 2" thick tapering to nothing. These are used to fine tune the height of the wing at the centersection spar and the tip. Now get a suitcase strap, rope or several belts and strap the inboard wing to the centersection spar. This stabilizes the wing against the centersection spar, and stops it from moving fore and aft and in sweep while you adjust the tip and root for correct relationship to the spar. Cinch the straps tight, double check that the wings fit well to the centersection and especially important the the incidence is correct (of course, the fuselage must be level). Four large 'blobs' of bondo (about 3/4" diameter) are placed roughly above and below the hard point. Allow this bondo to cure completely, before you attempt to drill the 6 mounting holes. Now, run your long 1/4" drill through the centersection spar and drill through the "hard points" in the wings. You are now ready to enlarge all six holes to 5/8" diameter, using your spotface tool. As you drill into each "hard point" the 5/8" spotface will break through each lamination of glass and aluminum. You will find that the spotface will break loose a thin "washer" of glass or aluminum located on its cutting edges each time it breaks through a layer. At this point it can no longer cut, and you must withdraw the tool and remove the small "washer" or "disc". Do not try to drill all the way through one hole in one operation. Clear the spotface often, and every time it breaks through a layer of glass or aluminum. It is a good idea to move from one hole to another to allow each hole to cool off. You must not get the wing fitting area hot, so go slowly and carefully, clearing often, and if necessary, stop and allow things to cool. We have found that this entire set up, jigging and drilling both wings to the centersection, takes about 5 hours, 2 hours just for

drilling. If you are building your Long-EZ in a 2 car garage, you will have to take it outside to do this set up. Be sure to protect the fuselage and wings from direct sunlight with white bed sheets or newspaper.

We found that our spotface tool tended to bore a hole as much as .007" over its intended .625" size. This results in a loose fit on the LWA9 bushings. It is satisfactory to fill this void with wet flox when installing the bushings. It is recommended that this flox be cured while the wing is bolted to the centersection spar. This assures perfect alignment of the bolt holes.

FINISHING - CAUTION! Do not ever wipe paint thinners on any part of your structure. Minute pin holes in the epoxy/glass skin can allow the thinners to penetrate down to the styrofoam, which dissolves in thinners. This can cause the skin to debond from the core. For the same reason, care should be taken to fill any possibly dry areas (presence of air voids) or areas with pin holes, with epoxy, before applying featherfill or primer, both of which contain solvents that can attack the styrofoam. Epoxy wiped onto the surface with a rag should be sufficient to seal layups that otherwise maybe dry enough to allow thinners or primers to penetrate. The surface must be sanded after epoxy cure.

MAIN GEAR ATTACH - A builder has suggested using left over scraps of R45 (dark blue) foam in the landing gear attachment area where we call out using urethane foam. This is fine, although not as easy to carve down to the wood longerons as the urethane.

AILERONS - Use care on the leading edges of ailerons to get the full radius around the mass balance without a sharp edge. A sharp edge will cause early airflow separation on the up-deflected aileron and will reduce roll power.

SKETCH OMITTED

LANDING BRAKE INSTALLATION - Page 24-1, the sketch showing LC1, does not show the cutout necessary for the seat belt clearance. Before bonding LC1 into place, make the cut out per the right side.

SPEED BRAKE RIGGING - Due to the fuselage bottom on the Long-EZ being thinner than the VariEze you may have to shorten the LB21 pushrod (turn a few more threads on it with a die). When rigging the speed brake, be sure to obtain the correct amount of offset with the brake in the down position. The top rod end must be 0.4" aft of a straight line drawn between the upper and lower pivots. It is acceptable to vary the 0.4" dimension + or - .1" as required to obtain the 40 lb. brake closing force.

SKETCH OMITTED

LONG-EZ COM ANTENNA - At last, a high performance com antenna. Jim Weir from Radio Systems Technology developed a com antenna for the Long-EZ that fits in the winglet. (see photo) We have tested it in the Long-EZ N79RA and found it to have excellent range. We were able to use it at distances of over 80 nm. The antenna uses copper foil and RG58U lead in. It does not require a ground plane. It can be

installed on the foam core before glassing and is completely enclosed within the winglet. Ours was placed on the outside skin after drilling some carefully-aimed holes. Install the antenna system before glassing the inboard side of the winglet. Cut 2 strips of copper foil 20.3" long, remove the protective backing and stick the foil to the foam one inch from and parallel to the trailing edge. Measure the rudder cut out area and bend the lower (2") end of the foil forward to miss the rudder. From where the two foil strips come together cut a slot just deep enough to hold the RG-58U/A lead in cable flush with the foam surface. Hold the lead in with toothpicks similar to the method used on page 19-7 rudder conduit. Be sure the three Ferrite Balums are installed just above the connection as shown. Solder the center wire of the RG-58U/A to the top foil strip and the outside "ground" braid to the lower foil strip.

Be sure the upper and lower foil strips don't touch or short out. Use about 1/8" separation. Check that none of the wire, ferrite balums etc. stick up above the foam surface, trowel in dry micro around the solder joints and other voids and glass the inboard winglet as per the plans.

Coil up the excess cable and thread it through the wing during winglet installation.

The antenna kit is available from:
Radio Systems Technology
10985 Grass Valley Avenue
Grass Valley, CA 95945

Antenna kit price -
Assembled - $25.50
(with BNC connectors)
Unassembled - $15.00

SKETCH OMITTED

CP26, page 7

NOSE TIE-DOWN FOR THE NOSE-DOWN PARKING

In order to tie your Long-EZ or VariEze down when parked nose-down (best way for high winds), we recommend installing this simple tie down, which is located at F.S. 1.5" and W.L. 8.9". The tie down consists of an aluminum tube floxed into a hole in the side of the nose, oriented horizontally. A removable steel tube slides into this aluminum tube and locks with 90 degrees of rotation. The steel tube protrudes approximately 2 1/2" out of the left side of the nose, and has a steel ring welded to it, so that when the steel tube is pushed in, turned 90 degrees to lock, the steel ring points at the ground.

SKETCH OMITTED

Materials required:
Part #NTDA 1 pc. 7/8" O.D. x .058" wall x 7 1/4" long, 6061-T6
aluminum tube
Part #NTDB 1 pc. 3/4" O.D. x.049" wall x 10" long, 4130N
steel tube

1 hardware store type 2" diameter steel ring (3/16" or 1/4" wire size)
1 AN3-11A bolt
1 MS21042-3 nut

On a new Long-EZ, the best time to install the nose tie down is in Chapter 13, page 11. With the top of the nose cut off to fabricate the nose door (step 9), drill or cut with a dremel a 7/8" diameter hole through the left side at F.S. 1.5" and W.L 8.9". This hole must be drilled through both NG30's as well. Before installing NDA tube, drill a #12 hole through it, 3/4" from the inboard end. When you slip the NTDA tube into the holes it should lie right against the NG31 bulkhead. NTDA should be sanded dull with 220 grit, and should be floxed in with wet flox. One ply of BID should be layed up over the tube onto the NG31 bulkhead on both sides. Orient the #12 hole vertically and install the AN3-11A bolt and nut. Allow this to cure.

NTD-B is a 10" long piece of 4130N steel tube with a 2" diameter hardware store steel ring welded close to one end per sketch. The other end is slotted and notched so that the ring is held horizontally facing forward, while NTD-B is slipped into NTDA. The slotted end locates over the AN3 bolt, then the NTD-B tube is rotated 90 degrees to orient the ring vertically down, pointing at the tie down.

To park the airplane, park it with the tie down ring directly over the normal "tail" tie down rope, and snub it down firmly. The large ring allows you to use ropes or chains normally found at airports.
SKETCHES OMITTED

VARIEZE BUILDERS

Installation of Cowling Trailing Edge Closeout. This cowl is not supplied with a trailing edge close out piece. This is custom-laid by the homebuilder to assure an accurate fit.

Apply shiny-surface grey duct tape on the inside TE of the bottom cowl half as shown. Sand dull, the top cowl TE. Jig TE down, with the TE taped together and with the front opened 8 1/2" as shown. Cut 10 strips of 45 degree BID 4" wide and 24" long and 2 strips of 45 degree 3" wide and 24" long. Now, layup the 5-ply BID TE close out. Cure, then pop off the bottom cowl and layup the 1 ply BID ply lapping onto the top. Trim the closeout to 1.6" as shown. This TE close out will have four equally spaced fasteners on each side. (three for Long-EZ).
SKETCHES OMITTED

VARIVIGGEN NEWS by Mike Melvill

In early September this year, I was fortunate enough to travel to the east coast (airlines, not by Viggen!) where I visited with Arthur Schwartz, whose VariViggen was ready to fly, at the Soffolk County airport on Long Island.

As you can see from the photo Arthur's Viggen, N37678 is a fine looking aircraft. He had already weighed the plane several times on two

different sets of scales, his Viggen weighs 1154 lbs (empty weight), and his cg came out very well. We spent several hours going over the control system, and generally checking the security of everything. Arthur had done an excellent job, so any further dilly-dallying was only wasting time. We gassed it up and I "drove" it around on the ramp and taxi-ways to get the feel of it and to familiarize myself with the cockpit and systems.

A couple of high speed taxi runs down the runway, lifting the nosewheel off, felt really good, the Viggen tracked straight as an arrow and has effective brakes. I taxied back to where Arthur was standing on the ramp, and told him to get his camera ready.

The tower cleared me for take-off so I taxied out onto the runway and lined it up with the centerline. Power was brought smoothly up to full throttle and acceleration felt about the same as mine (N27MS). The most noticeable thing to me on takeoff was the relatively flat deck angle at lift-off compared to N27MS. Arthur's Viggen has the S.P. outboard wings, N27MS has the standard wings. The difference in pitch attitude at liftoff is almost 3 degrees due to the SP wing and the fact that Arthur's Viggen is almost 100 lbs lighter than mine. He has a Lycoming O-320 160hp. Even so, Arthur's Viggen was airborne considerably before I expected it to be. My Viggen is normally rotated to what seems like a very steep angle (6 - 7 degrees) then it rolls for a while on the mains before the wings take all the weight, and it lifts off. Someone familiar with a standard wing VariViggen, flying an SP wing, will be surprised when it "levitates" into the air at a relatively low angle.

After lift-off, the airplane felt solid and responsive. I rocked the wings briefly, pitched it up and down, asked myself "was I holding the airplane one way or the other?" The answer was no, it was in excellent trim. I continued the climb to 3000 ft above the airport, where I throttled back to keep the airspeed from going over the gear down speed of 125 mph. I flew around for 40 minutes, generally checking trim roll response, pitch response and control authority. The engine ran flawlessly, all temperatures remained in the "green". The first landing was amazingly easy, even easier than N27MS, there is a tendency to float if you are too fast, but it lands very slowly and uses very little runway.

We looked it over carefully, added a little gas and I went up again to look at stalls, slow flight etc. The SP wing and lighter weight is very noticeable in low speed performance. It hung on with no problem down to 40 mph indicated. This is below normal stall speed, so there must be some system or indicator error. N27MS will fly at 55 mph indicated, although at a higher angle of attack. The biggest difference between the SP wing and the standard wing in the stall is that if you get the controls crossed the SP will drop a wing, the standard will not.

One strange thing showed up on Arthur's Viggen. I was not able to go very fast due to the decision to leave the gear down but at 110/120 mph at higher power settings in level flight, there was a noticeable tendency to pitch nose down, something my Viggen or Burt's Viggen has never done. Even at 200 mph indicated. This remained a mystery until after I returned to Mojave.

Unfortunately, the next morning while taxiing very slowly, the right main gear collapsed, due to the pin in the cable pulley, (first edition plans, cable driven main gear) shearing, which allowed the down lock to disengage. When I turned left, the right gear folded inboard, allowing the airplane to come down on the right wing tip, breaking off the lower winglet. Needless to say, this put a stop to further flight testing, so I returned to Mojave.

I am happy to report that Arthur has already repaired it and has about 6 hours on the airplane at this time. He has now raised the gear and has been able to increase his speed, however still is getting the nose down trim situation. While on the phone to him last week, Burt and I determined that instead of 2 degrees of down thrust, Arthur had inadvertently built in 2 degrees of "upthrust"! This is probably the reason for the nose down trim he is seeing. Arthur has promised us a report as soon as he has checked it out.

FLASH!

Just received more information from Arthur. He made external templates of his outboard wings and from these we have determined that he does not have enough 'washout' outboard of the ailerons. In fact this deficiency in washout calculates to be equal to 3 degrees of reflex. This together with the "upthrust" he had built in, undoubtedly accounts for the nose down pitching moment. We have given Arthur the information he requires to correct the problem, and will report on his findings as they become available.

This does bring up an important point, and we should all learn from this example. Just prior to glassing the top of your outboard wing, you must check the washout. This is done by putting the inboard and outboard hot wire templates back onto the foam cores and checking that the waterlines (level lines) are level to each other. This is extremely important. Do not omit this step! Once the top skin is on, this is very difficult to correct.

Oshkosh '80 - Sally and I flew out in N27MS and we flew in loose formation with Burt and Pat in the Defiant. We had an outstanding trip, flying from Mojave, via Zion National Park to Page, AZ. We then flew up the length of Lake Powell (unbelievably beautiful) directly over the continental divide to Denver, where we had lunch. From there to Omaha where we spent the night. The next morning we flew directly to Oshkosh, arriving at noon on Friday. N27MS performed well with the exception of wearing out a brush in the alternator just after leaving Omaha. The nice thing about having a 35 amp hour battery is that it presented no problem and Alcor supplied us with a new brush free of charge at Oshkosh (old one was defective).

While at Oshkosh, though the starter went bad, but again we were fortunate enough to be able to obtain a replacement through Basler, the FBO at Oshkosh. I flew the Viggen in the fly-bys several times and in a three ship formation demo four times during the week. We had a lot of Viggen builders come by the airplane and the RAF booth, and quite a few builders are getting close to flying. It was great to be able to chat with so many guys at one time who were building the same airplane.

We at the RAF booth and myself especially, were extremely busy all week and really was sorry not to be able to spend more time with Viggen builders, maybe next year we can set up a day or two where we could have a bull session on the flight line at N27MS.

Other than very bad weather for the first two hours (we made two 180's!) we had an excellent flight back to Mojave via Rapid City, S.D., Salt Lake City, Utah and Las Vegas, Nevada. We put 30 hours on the Viggen and she now has 460 hours total.

VARIVIGGEN PHOTO OMITTED

ACCIDENTS

The CP Newsletter reports accidents and discusses their conditions and causes for information purposes for all operators. We have always investigated accidents in the interest of determining information that we can disseminate to you to prevent recurrence. It should be recognized in our discussion of accident conditions or causes that generally this information is preliminary since it is published before the availability of the FAA accident report.

1) An Illinois VariEze crashed on landing approach, fatally injuring the pilot/builder. The pilot had turned sharply from a low slow downwind and failed to upright the aircraft. Impact was 150 feet short of the end of runway. Weather conditions were low ceilings and strong gusty direct crosswinds of about 25 mph. The pilot was thrown forward through the instrument panel and clear of the fuselage. The seat belt (EON 8000 type 4) was found open. (see CP 24 page 4). This airplane had previously been damaged when landed short of a 5000 ft runway.

2) A VariEze crashed as it entered the downwind leg of the busy approach pattern at the Oshkosh EAA convention. The aircraft was observed to maneuver erratically then turn and dive at very high speed, with high power maintained to impact. Both occupants died immediately. The aircraft struck a concrete street in a near vertical (60-70 degree) dive, at a low angle of attack. A pilot witness 200 feet away observed that it did not appear that the pilot was attempting to pull out of the dive. This points to a possibility of either a pitch control system disconnect or pilot incapacitation. All but two parts of the control system were found - they did not indicate control system disconnect. The aircraft did not have a rear seat control stick. Thus, pilot incapacitation is the suspected cause.

Destruction of the aircraft was unbelievable, only small parts remained. The engine struck the concrete road at the same point that the nose did. The bow shape of the main gear strut was clearly imprinted on the concrete at the impact point.

Initial investigation at the scene of this accident suspected fuel starvation because there was no evidence of fuel and there was no fire. It was determined that the tremendous force of the estimated 200 mph impact resulted in a fuel and oil explosion, however there was no resulting fire. There have been no fires associated with any VariEze accident.

3) A Washington state VariEze crashed on approach while making a series of touch and go circuits. It was observed on a high final when the pilot initiated a sideslip. The airplane then rolled inverted and the pilot attempted to pull out in a reversing direction. Insufficient altitude was available for the pullout. The aircraft struck the ground in a near level attitude removing the landing gear and the bottom of the fuselage. The pilot's injuries were fatal. The departure that rolled this aircraft over appears to be the winglet stall discussed in CP #22 page 7 and 8. While the pilot appears to have disregarded the operational limitations recommended, this still should not have resulted in a departure. We intend to inspect the winglet contours of this aircraft to determine if any variances may have changed its susceptibility to winglet stall.

To prevent possible recurrence of this type of accident we urge all VariEze operators (does not apply to Long-EZ or VariViggen) to again review the information on page 7 and 8 of CP 22. Check your rudder rigging, wing cuffs, and winglet contours. In addition, to determine the actual departure susceptibility of your particular aircraft, conduct the following test at an altitude of 10,000 feet: full rudder sideslip, abruptly applied left and right at speeds of 100 kts, 90 kts, 80 kts, 70 kts, and full-aft stick. Your airplane should yaw, under control, with no tendency to stall or roll off. If your airplane has any undesirable characteristics, report these to RAF so we can analyze the causes and the extent of any variations.

4) A VariEze pilot ran out of gas on an extended trip. He selected the fuselage tank, restarted the engine and continued, overflying one airport, attempting to stretch his range to another. Total fuel depletion occurred several miles short of his destination. His forced landing was downwind in a turn. The airplane was damaged extensively and ended upside down. There were no injuries.

5) A Nebraska VariEze equipped with the original 2-ply tires, was making a gross weight takeoff. The pilot began rotation at 85 or 90 mph, (above the normal lift off speed of 75 mph), when the right tire blew. He aborted the takeoff, using left brake all the way to stop to maintain directional control. He reported it was not hard to control even though the right brake bleed failed and the right wheel pant and brake rotor was destroyed. His gear strut was the original configuration, not reinforced. He placed the right wheel up on a dolly tilting the aircraft with most of the weight on the left wheel, then pushed it half mile to a hangar. On arriving, the left gear strut buckled a few inches above the axle, inside the tightly-sealed, non-vented wheel pant. The cause of the strut failure was heat. The long, continuous high speed braking resulted in a very hot brake. This heat, sealed in by the wheel pant, slowly permeated the fiberglass strut allowing it to soften and buckle under load. Lessons learned: Do not use the two-ply tires. Ventilate the top of your wheel pants. If unusually heavy braking is done, 'set' the gear to relieve load or jack the airplane to relieve stress while the strut cools. Glue a piece of your fiberfrax fire wall insulation material to the strut (use silicone rubber adhesive) adjacent to the brake disc. Your VariEze and Long-EZ should lift off and land at under 65 kts and 60 kts respectively, unless you have an airspeed instrument error or airspeed position

error. Leaving the airplane on the ground above this speed increases tire stresses and reduces tire life.

B & C Speciality Products has developed a lightweight aircraft power generating system. This system was specifically developed for today's weight-sensitive homebuilt designs and has undergone extensive in flight service testing.

Two models are available, one is a gear driven alternator. This bolts onto the alternator pad on the accessory case of the C-85, C-90 and O-200 engines. The other alternator is belt driven, designed for the Lycoming O-235. Can also be adapted for other engines. The complete alternator system weighs only 4 1/4 to 4 3/4 lbs., depending on the type of drive.

B & C Specialty Products,
518 Sunnyside Ct
Newton, KS 67114
(316) 283-8662

Note: RAF is currently testing the B & C lightweight alternators on our VariEze and Long-EZ. Their kit is very nicely done and easy to install. Performance and support by Mr. Bill Bainbridge has been excellent. Many of you saw these at Oshkosh.

PHOTOS OF B & C ALTERNATORS OMITTED

John Friling made his own lightweight alternator for his Continental powered VariEze. John purchased an alternator from a Yanmar Japanese garden tractor.
Part # 942131-41410 (stator)
Part # 942741-42299 (magnet wheel)
Part # 49-401-01 (Kohler regulator, 15 amp)
John used his old Continental generator shaft, bearings and flange, (see photos). John has a really nice set of drawings for those of you who would like to make one like his.

The Lycoming on Mike's Long. Due to the tight fit on many parts we are shifting the engine down and aft. These changes will be reflected on Brocks mount and on the new edition of Section IIC.

LONG-EZ

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE

The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE

At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY

The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to

27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES
Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other

prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system

and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 27. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 27. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 27. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 27. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 through 27.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins.

Saturday Demos - Every Saturday (except when gone to airshows) RAF conducts a demo at our shop at the Mojave Airport. We start the presentation/discussion at 10 am each Saturday with flight demos of our experimental aircraft at approximately noon (weather permitting).

Bring any of your parts for inspection. We are located near the west end of the flight line at the Mojave Airport about 2 hours drive north of Los Angeles on Highway 14. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

Mike and Sally's Long-EZ by Mike.
In CP 26 Sally and I were going at it as hard as we could to try to finish N26MS before the Bahamas Trip. Due to several circumstances,

some beyond our control, we were unable to fly our Long to the Bahamas, although we did manage to get a few flights on it prior to leaving on the trip.

We really burned the midnight oil the last few weeks and without help from Burt, Pat, Bruce and Giles, we would not have got it flying before leaving. We filled and primed all the parts and then transported it down to Mojave Airport, where we finished up engine baffling and wiring. On Sunday, 21 December we finally had it all done. We put 10 gallons in each fuel tank, flushed the fuel system thoroughly and started the engine. Since Sally and I overhauled the engine, it was a great relief to have it start and run so smoothly! We ran the engine for half an hour, then after conducting a careful weight and balance, determining that the cg was in the center of the first flight box for me, I taxied out for the first runway flights. I made 3 runs down the runway, checked brakes, rudder effectiveness, rotation speed and on the 3rd run lifted off a foot or two. It felt absolutely great, it was straight, no trim required, so I landed, taxied to the end of runway 12, and with Dick and Sally in Burt's Long-EZ on my right wing, I took off.

It felt absolutely right. It is a difficult moment to describe on paper, when you depart the runway environment completely, and commit yourself and your new airplane to the air, it is an incredible feeling. All engine instruments were in the "green", so I climbed on up to 5,000 feet and carefully explored various control inputs and power settings. I am delighted to report that it required no trim to fly straight and true. I flew about 40 minutes, landed and Sally made the next flight. She is also delighted with the handling qualities. Just before dusk Burt took it up and was pleased with it.

Since getting back from our Bahamas trip we have been putting hours on our Long. I have opened the envelope up to 185 knots indicated at 9,000 feet and she loops and rolls beautifully. The roll response is even better than the prototype N79RA. With no wheel pants, the large 500 x 5 tires and no spinner, speeds are not very meaningful, but at 7,500 feet she trues out at 151 knots (173mph), so I believe that with wheel pants, a spinner and a magneto that sparks on all 4 cylinders our Long-EZ will be at least equal to the owners manual, possibly a little better.

Evaluation of N26MS by Burt
Sally and Mike built this one with alot of attention to accuracy. The reward is an airplane that flys ball-centered at neutral roll trim, hands-off. Its roll qualities are crisp with minimal adverse yaw. Pitch handling is solid with firm speed stability. Stalls are optimum - a very mild pitch bobble at full aft stick. Roll reversals and sideslips performed at full aft stick are smooth and do not produce wing rocking. Engine noise and vibration are lower than the prototype due to the dynafocal mount. A superb flying airplane, the best of any type I've flown.
Back to Mike. - We will continue to report on how it goes, as we accumulate time and data.

Before final assembly we got a few more relevant weights:

Wings with ailerons and rudders complete

(before finish)	64 lbs. each
Rudders	
(filled and painted	1.2 lbs. each
Left elevator	
(filled and painted)	3.5 lbs.
Right elevator	
(filled and painted)	3.0 lbs.
Ailerons, with hinges,	
universal and torque tube,	
(filled and painted)	5.4 lbs. each
Canard with fairing cover	
(filled and painted)	18.5 lbs.
Canopy, with hinges	
(filled and painted)	17 lbs.
Wings with winglets, no rudders,	
no ailerons (filled and painted)	60 lbs. each

We ended up with a total of 1,200 hours. This included all man hours put in by everyone who worked on the airplane. This also includes overhauling the engine, developing the new engine mount and baffling, installation of such things as tape deck, intercom and what Burt calls "fru-fru" (non-essentials). See page 4 of this newsletter for Burt's comments.

CROSS COUNTRY IN A LONG-EZ by Mike Melvill

Due to our Long-EZ not having all the hours flown off in time for the Hospitality Club fly out to the Bahamas, Burt very kindly let Sally and I use N79RA. While I have quite a bit of flying time in Burt's Long, it has all been around the airport, this was my first long cross country in a Long-EZ.

To say that I was impressed would be putting it mildly., This is absolutely the nicest cross country flying machine I have ever flown. At 9,500 feet we trued out at 158 knots (183 mph) at approximately 72% power. At sea level, full throttle we trued out at 169 knots (194 mph).

We flew 3 legs of 5 hours and one of just over 6 hours. We were extremely comfortable at all times. Cabin noise level is a little high and a good noise-attenuating headset really is a must. The tremendous range is something I have not experienced before and there is a lot of comfort in knowing that you can fly for 7 or 8 hours if you have to, particularly in a bad weather situation. We generally had great flying

---

weather, but on the way back Sally and I ran into about four hours of marginal VFR, low ceilings and occasional low visibility in rain. It was great to know that we could turn around or fly around virtually any sized weather system, without having a fuel problem. We flew in loose formation with Burt and Pat in the Defiant on part of the trip, and on one occasion we had to stop because the Defiant was getting low on fuel! Sally and I shared the flying almost equally and I was pleased to find how comfortable I was even in the back seat. I spent 17 1/2 hours there! On one leg, from Las Cruces, New Mexico to New Orleans,

Louisiana, a distance 1016 sm, the Defiant and Long-EZ went together non-stop at 9,500' and covered the distance in 5.1 hours, a ground speed of 199 mph! During this flight in smooth air several times, I did not touch the controls for an hour at a time, a super airplane. Total trip distance, including sight-seeing and demos was 6440 statute miles. All we did was add fuel and oil, no maintenance of any kind was required. N79RA how has 493 hours, averaging nearly 1 hour per day since first flight in June 1979.

CONTEST TIME!!!

We have had many requests for a Rutan Aircraft jacket patch, and of course we do not have such a thing. We will give a prize to the winner of the "Patch Design" competition, in the form of a New Mexican, laminated silver belt buckle, your choice of VariViggen, VariEze or Long-EZ on the buckle and a ride in Long-EZ here at RAF in Mojave. What we would like to see is a stylized or futuristic patch depicting Burt's canard type airplanes, or whatever you talented artist type builders can think of. Submit your ideas to RAF by March 30th 1981, and we will announce the winner in CP 28.

Peter Calvert of Leicester, England flying his VariEze, G-LASS, recently set two World records in Class C sub Class C-1-A.

1) Speed over a recognized course, Malta to London 145.05 km/h
2) Speed over a recognized course, Ajaccio to London 155.37 km/h

While the speeds may appear a little slow, Peter had to stop enroute twice for customs, fuel and the men's room, each stop of about 1 hour. Congratulations Peter.

Tom Garrison - Route "S" Box 80, Tulia, Texas, 79088 is trying to get a Long-EZ/VariEze group together in the Texas panhandle area. Any builders interested please contact Tom at the above address.

THE EZ BAHAMAS ADVENTURE - by Bruce and Bonnie Tifft

Island Hoppers:
Mule and Debbie Ferquson, Boomer, NC (Debbie flew commercially to the island, while Mule carted his guitar in the back seat of the EZ)
Ed and JoAnne Hamlin, Rocklin, CA
Jim Heitkotter and June Hartley, Fresno, CA
John and Mary Jackson, Jackson, MS
Byron McKean and Diane Meader, Seguin, TX
Mike and Sally Melvill, Tehachapi, CA
Dave Langston, Georgia and Jeff Rose, Chattanooga, TN
Norm Ross and Glenne Campbell, Victoria, BC, Canada
Burt Rutan and Pat Storch, Mojave, CA
Bruce and Bonnie Tifft, Ventura, CA
Earl and Barbara Wilson, Citrus Heights, CA

It is indeed a difficult task to attempt to relate the many wonderful experiences, feelings and thrills associated with this particular EZ adventure. However, we will try to recapture and share some of the highlights on the trip.

Our adventure started on the crisp, clear dawn of Saturday, December 20th. Anticipation and excitement filled us as we took off from Santa

Paula Airport, on a trip that we and others had been planning and scheduling for over a year. First stop - Las Cruces, NM and a warm and friendly reception from EZ Hospitality Club members Joan and Charles Richie. Super Mexican dinner at LaPosta (afraid the Richies were saturated with Mexican food by the time the other migrating EZs passed through). We were joined in Las Cruces by the Northern California contingent, Ed and JoAnne and Earl and Barbara (lo and behold, not another yellow EZ - beautiful). This was Earl and Barbara's first trip after frantically getting their plane signed off in time for the journey. Ed did the navigating and led the way allowing Earl to concentrate on flying his shining new bird.

Next stop - - - New Braunfels, Texas. As we open the canopy we hear Christmas music over the loudspeaker and a grinning "real live" Santa Claus, alias Byron McKean, welcomes us. They don't exaggerate when they talk of Texas hospitality. It was great!

We again join up with the Hamlins and Wilsons in historical New Orleans on Christmas Eve. With the gracious assistance of Club member, Dewey Straley we enjoyed a delicious Cajun dinner at Berdous Restaurant and then real "southern comfort" at the Straley home. A gathering of EZs took place Christmas Day as Byron and Diane arrived at Lakefront Airport. Shortly after, the Louisiana sky was filled with the roar of the arriving Defiant and Long (Burt, Pat, Roger, Mike and Sally). Christmas evening was spent taking in the intoxicating atmosphere of the French Quarter with some fantastic jazz at Preservation Hall and then on to Pat O'Brien's for a roaring good time.

Burt, Pat and Roger, desiring some over-the-water experience, navigated the Gulf of Boca Raton. The rest of us, having only one engine, meandered in groups along the coastline to Ft. Pierce, Florida. Our timing was incredible because as we were flying over Ocala, Florida, we happened to catch the Southern contingent grouping there (the Jacksons, Mule, Dave and Jeff).

St.Lucie County Airport was bustling with EZs from all over the country as we arrived (by the way, Sally was front-seat pilot of the Long on this leg of the journey). Many of the local Club members were there to welcome the group. Our Bahamas Tourist host, Marshall Dent, was also on hand to haul us all to the Holiday Inn. (At this point, we must extend our very special thanks to Norm and Gertrude Dovey for rescuing the "BEEZ"). After an excellent steak dinner and a round of introductions, pilots and crew tackled the job of getting 9 EZs, 1 Long and 1 Defiant across the Atlantic to Andros Island. After a great deal of discussion (can you imagine all these "individualistic" individuals trying to come to a single solution!) it was decided to have three separate flying groups. The Defiant would lead the way and check weather, etc., and report to the others. Radio channel 123.4 was filled with chatter between the Blue, Yellow and Red flight groups. It was an incredibly beautiful flight and all three groups successfully invaded the sleepy island of Andros (no one had to test the "floatability" of their plane).

Although the clouds hid the sun from the island for the first few days, the group jumped in with both feet and went native. Perhaps the following will give you a few glimpses of the activities;

Norm, Glenne, Bruce and Bonnie bicycling in the rain.
Pat and Sally not able to resist the temptation to swim in the aquamarine water in their undies. (Sorry for squealing on ya' ladies).
Barbara sitting in the "Yellow Tuff" at Ft. Pierce making sure, at long last, that she made it to the Bahamas.
Ed trying to calm JoAnne down after she was greeted by a big green frog in her bathroom.
John trying to talk someone into playing doubles tennis so he didn't have to face Mary alone.

Mike, Burt and Norm in one very small sailboat going out to the reef for some fantastic snorkeling.
June and Jim bicycling a very long distance and being rescued by a friendly van driver who hauled them and bicycles back to the hotel.
Byron jogging down the runway in the early dawn accompanied at various times by Jeff, Burt or Bruce (where were you, Diane?).
Mule entertaining the entire hotel with his guitar medleys. Of course, everyone joined in the singing including Maurice (a friendly gent from Montreal) who sang the old hillbilly tunes in French.
The whole "nutty" group building a 6 place sand EZ on the beach, conch shells for strobes, whiskey bottle for pilot tube?
Dave diving for conch shells and conning Mule into hauling them back for him.
John and Jeff taking a "walk" by the "topless" girls on the beach.
22 nuts in one van coming back from the beach.
The group terrorizing the poor controllers at Nassau International Airport who kept insisting that we where all Defiants or referring to us as "small jets".

The group departed at different time intervals and started winging their way homeward. It was indeed a wonderful adventure; one I am sure we will all remember and cherish for a long time. The thrill of flying the planes across the United States, combined with the friendship and fellowship of the Club members and people along the way, made for a holiday that will be very hard to top! To answer the question everyone was asking, "WHERE TO NEXT?" Our reply, we haven't the foggiest notion. ANY SUGGESTIONS??

For Norm Ross and Glenne Campbell, with their 1979 Oshkosh Grand Champion VariEze, Bahamas was just a jumping off point on a more extensive trip. Pegasus, based in British Columbia, was going on the longest trip yet flown by a VariEze. Traveling is not new to Pegasus, having flown 420 hours (70,000 miles) in the 17 months since Oshkosh '79. The following is Glenne and Norm's story:

Bahamas Adventure follow up -
Just hours before press time Norm and I have arrived in Mojave to catch Bonnie's report on the EZ Bahamas Adventure. As a follow up to her quest 'where to next' we'll report a sampling of what goes on further south.

Pegasus and crew departed Andros Island and Eze people accompanied by Mike and Sally as send off party. We flew down the colorful cays to Exumas Island, landed, dined, refueled and shared fond farewells. As

Mike and Sally 'rolled out' I held my breath and maintained (?) disbelief in the safety in numbers theory. Norm and I caught a ride into Georgetown, the village haven of royalty from all over the world. Truly a beautiful location with a variety of affordability and activity.

Onward the following day we flew down the cays, refueled at Great Inauga, and onto Port au Prince, Haiti. To our surprise the Haitians speak very good French, a lot of Creole and some English. There we refueled and climbed out to make our journey high above the clouds to Kingston, Jamaica. No worry of flying over the water this leg of the journey as the cloud cover was so thick nothing below was visible. The tell tale sign of land was a square inch of mountain peak off in the distance. Norm's navigation brought us right out over the top of Kingston where the clouds cleared for eze access. Jamaica was interesting. We had to pay a dollar each to ride in a van with 20 others to town. General aviators are not warmly received in Jamaica. Landing fees are twenty dollars, you must clear health and pest control (the aircraft is sprayed) as well as security, immigration, and customs - all very time consuming. All flights in Jamaica require inward and outward declaration, flight route clearance, and customs clearance. We were not allowed to fly to and land at the town we had plans to meet friends at so had to leave the plane at Montego Bay where security was assured but left us 'uneze'. We travelled 50 miles by taxi in the dark to Negril on the west end of the island. Accommodations there are plentiful but must be sought out as the natives rent rooms and camping space. The head of every Jamaican family will tell you that Jamaica is a place to "cool the brain", but don't plan on doing it in the cool of the evening as every family has an assortment of at least five skinny dogs to act as doorbells, night watchmen and alarm systems from sundown to sunup.

Needing a rest, we returned to MoBay, cleared customs, recovered our wings and departed for the return stretch of our journey. Back in Haiti we stayed overnight in a motel "on the hill" where we met numerous people from around the world, each in the country for a different purpose. It was there someone suggested we visit Santo Domingo on the south cost of the Dominican Republic. We flew there via Cap Haitian, Haiti, where the eighth wonder of the world sit perched upon a mountain top as the citidel built to protect the natives from reinvasion of the French many moons ago.

Santo Domingo is the location of Christopher Columbus's discovery of the western world. We landed at Las Americas airport, here most (excluding American Airlines employees) speak Spanish. Fortunately a young fellow befriended us and assisted us through customs etc.

Unfortunately we felt the need to return to the continent so didn't spend time in the city which looks to be very interesting historically and culturally.

Our return flight took us Santo Domingo - Great Inauga - Fort Pierce - an so far Mojave. Many thanks to Norm and Gert Dovey, Jack and Marilyn Day and Harry and Donna Bush for their fine hospitality. By the time we touch down home at Victoria B.C. we will have covered 11,000 miles and as Bonnie says "Where to next?" Any suggestions??

Tips for Caribbean travellers:
- inward and outward general declarations are required by each country. These are available from AOPA.
- file flight plans, keep tanks full of fuel.
- have a good communications radio
- VORs are few and far between
- speak some French and Spanish
- carry a good Caribbean guide, such as Fodors.

Best wishes, Norm Ross and Glenne Campbell.

International VariEze Hospitality Club Fly-in

Organizer: Charles and Joan Richey,
(505) 523-1300
Camping and Condo's in Alpine Ski Valley
Cookout planned.
4th and 5th July 1981.
Taos Ski Valley, New Mexico, fly in to Taos Airport.

NACA FLUSH INLET

Steve Woods and Tim Gheres (address: Wood & Gheres Inc. 105 Appleblossom Court, Orlando, FL 32807) are selling plans and providing builder support for those builders installing flush inlets. (see CP #26).

Mike installed one on his Long-EZ and used a 12 inch wide inlet, rather than the 14 inch size suggested for the 0-235. His 0-235 runs cool. We recommend using the 12 inch configuration for the 0-235 Lycoming. Mike also installed an access panel aft of the main gear strut in the "top" (bottom?) of his NACA duct. This panel is an oval shape, 5" x 10" and is constructed and installed using the same method shown on page 13-11 for the nose door. This allows inspection of main gear attachment and access to plumbing and wiring normally only accessible through the hole in the back seat bulkhead. This same panel can also be installed on a Long-EZ (or VariEze) without the NACA inlet, in the same place. Do not make the entire area removable this cover area is required for structural reasons and should not be omitted.

Plans for Installation of Lycoming Engines in Long-EZ

As many of you know, we have not had a Lycoming engine section available since June. Section IIC was written in 1977 by an outfit on the east coast who first developed the Lycoming VariEze installation. We found many fit-related problems with this section when we used it to install the engine on the Long-EZ prototype, N79RA. Also, the Long has a number of major changes involving the fuel system, exhaust system, baffles, dynafocal mount and carb controls. Since it was evident that major changes were needed and that some of them would have to be flight tested, we decided last June to use Mike's Long-EZ to check the changes and to hold up printing the new plans until every detail had been flight tested.

Presently, Mike's engine is being fitted with EGT and CHT probes on all four cylinders to check inlet distribution. By the time you read this all testing will probably be complete. Because of the extent of the revisions, we will be publishing an entirely new section, Section IIL, for Lycoming. Section IIL will be available in early February 1981. As soon as it is received from the printer it will be mailed to those who have a Section IIC on back order.

Some of you Long-EZ builders have purchased, and received a Section IIC before the supply ran out last June. Do not use IIC to install your Lycoming in a Long-EZ. Return your IIC to us, we will replace it with a new IIL at no charge.

IMPORTANT WEIGHT INFORMATION - LONG-EZ

The most disappointing thing about the VariEze experience has been the general lack of adequate weight control by most builders. It is necessary to use diligence in controlling and eliminating each gram in order to avoid an undetected growth of many pounds. It is a reliable prediction the many Long-EZs will be built over-weight and be limited to short range or single-place operation. An equally reliable prediction is that many Long-EZs will be built with little equipment, careful weight control, and will be considerably lighter than those now flying. They will enjoy a high useful load, great takeoff and climb performance and unexcelled range.

The following information is a complete analysis of the actual weight of Mike and Sally's Long, N26MS. If you are building a Long, it is very important that you study all this information before you plan your equipment installation that you be aware of the weight impact of any additional equipment. N26MS has excellent structural workmanship, thus, most airplanes with less attention to good layups will probably be heavier than the data shown below. Study the table below. Note particularly the magnitude of the additional equipment.

N26MS was built with two conflicting requirements that added considerably to its empty weight: (a) full electric start with large alternator, and (b) pilot weight of only 108 lbs. using no temporary ballast. While the heavy electric (number 4) and ballast provisions (number 7) had the major impact on their heavy final empty weight of 883 lbs., their utility has not suffered as much as one might think. The reason is the total weight of Mike and Sally is only 263 lbs.. Thus, using the 1425 gross (owners manual page 30) their allowable fuel load is 46.5 gallons giving 1,000 mile range at 75% or 1,550 miles at 40% power, with reserves. Their allowable fuel load at normal gross is 29.8 gallons. Consider this same airplane with two 190 lb. adults as crew and without the then unrequired number 7 ballast provisions. That situation leaves only 207 lbs. (34.5 gallons) fuel for a range at 75% of only 700 miles, with reserves, or 350 miles with a 1325 lb. take off. Obviously, with that 360 lb. crew weight strong consideration should be given to using the electrical system in number 2 and eliminating as many items as possible in number 6, and 8, to provide the high utility and long range available with the Long-EZ.

We encourage everyone to use the light electrical system as in number 2. This is the one installed in the RAF prototype N79RA. Then, add

only the equipment you absolutely need and diligently refrain from seemingly - "small" additions.

Note that it is possible and advisable to have the Nav, Com and transponder with the small alternator and have an empty weight of less than 720 lb. However, if your front-seat pilot weight is less than 170 lb., you should use the 25 AH battery in the nose and accept the 19 lb. increase. This will be needed anyway to balance the aircraft. Also, if you are a very light pilot (less than 150 lb), be prepared to suffer a large penalty in empty weight if you want to install an electric starter. The starter, ring gear, alternator, brackets etc. mount way back at station 150+ and will require nose ballast for light pilots.

If you are successful in obtaining an empty weight of less than 730 lb you can fly two 180 lb people with the full 52 gallons of fuel and attain over 1800 nautical miles (2070 sm) range at economy cruise - a feat considerably in excess of any other light aircraft.

LONG-EZ EMPTY WEIGHTS BASED ON N26MS

1.	BASIC EMPTY WEIGHT (BEW) VFR instruments plus g meter and turn/bank gyro. No starter and alternator, graphite cowling. All equipment and components per plans. Conical engine mount and ram inlet. No avionics, cabin heat or lights. Small motorcycle battery to power warning system and fuel pump.	693.4	lbs.
2.	BEW plus the small alternator (see CP 26), including wiring and regulator (4.9 lbs.).	698.3	lbs.
3.	Number 2 plus Com, Nav, Transponder and all installation misc. (15.4 lbs.).	713.7	lbs.
4.	BEW plus standard 60-amp alternator, starter, ring gear, belt, brackets, mounting hardware, regulator, wiring, relays and 25 AH battery (68.5 lbs.).	761.9	lbs.
5.	Number 4 plus Com, Nav, Transponder and all installation misc. (15.4 lbs.).	777.3	lbs.
6.	Number 5 plus additional equipment on N26MS including: 500 x 5 tires, dynafocal mount, NACA inlet, landing light, Nav lights, strobe lights, cabin heat, relief tubes, primer, intercom and stereo tape player (38.1 lbs.).	815.4	lbs.
7.	Number 6 plus provisions to allow Sally (108 lb. pilot) to fly at cg=102.2 (1.8" fwd of aft limit). Includes a second 25 AH battery, wiring and switches to use the second battery, and 15 lbs. of lead permanently installed in front of NG 31 Bulkhead (44.8 lbs.).	860.2	lbs.

8. Number 7 plus some extras added because they were nice and "didn't hardly weigh anything". Misc. ranging from small covers and aluminum knobs, to heavier upholstery and different fuel caps (12 "small" items 22.8 lbs.). 883 lbs.

Advanced Composite Lightweight Cowling.

Graphite (carbon-fiber)-reinforced cowlings for the Lycoming Long-EZ will soon be produced and available through Aircraft Spruce and Wicks. Differences between these and the standard cowl are shown below.

	Standard	Graphite
Materials:	Gel coat Glass Mat/cloth Polyester resin	Glass Cloth Graphite Cloth Epoxy
Weight:	18 lb	12 lb
Cost: (both halves)	Approx. $245	Approx. $360

We have tested a prototype of this graphite cowl and are pleased with it. The part numbers are as follows for all cowls, standard and graphite.

Part #	Materials	Aircraft	Engine	Top/Bot
CCT	Glass	VariEze/Long	Cont	T
CCB	Glass	VariEze/Long	Cont	B
LCT	Glass	VariEze	Lyc	T
LCB	Glass	VariEze	Lyc	B
LCT-L	Glass	Long-EZ	Lyc	T
LCT-LGrap	Graphite	Long-EZ	Lyc	T
LCB-LGrap	Graphite	Long-EZ	Lyc	B
LCT-Grap	Graphite	VariEze	Lyc	T
LCB-Grap	Graphite	VariEze	Lyc	B
LCB-L	Glass	Long-EZ	Lyc	B

Continental O-200 Engine for Long-EZ?

As you have read in recent CP newsletters we are strongly recommending the Lycoming over the Continental for the Long-EZ. This is not to say the O-200 will not work - its installation is well-tested in VariEze airframes and, with the addition of mechanical fuel pump should operate well. However, with the O-200 you may find it a difficult and expensive modification to adapt an approved mechanical pump. Also, you will not be taking advantage of our recent development effort the last six months in refining and flight testing all the components in the Lycoming installation (Section IIL). If you have an O-200 you might consider trading it up for an O-235. O-200's are bringing an excellent price now days.

FIBERGLASS LAYUPS

We have recently inspected some layups with unacceptable epoxy-to-glass ratios and improper fiber orientation. Aircraft structure, whether its fiberglass, aluminum, or welded steel must be built properly or must be rejected. It is not satisfactory to accept any critical part that has excess epoxy. On every part, be sure to do the squeegee test for a "ridge" - see page 3-11 step 7. Pull the squeegee along, stop and remove it and see if you have piled the excess epoxy up into a ridge. You must spend time with the squeegee pulling all excess off the sides if the test reveals a ridge. Do not attempt any layup (except small corner tapes) unless you have a clean, flexible, smooth squeegee to use. It is not possible to smoothly remove excess or determine correct ratio with a brush. When building any type of aircraft structure, your very best workmanship is just barely adequate. Do not accept anything less. Practice on your Chapter 3 flat layups until it is perfect before building aircraft parts. If in doubt on how a given layup should look, duplicate it on a small piece and send it to RAF for our comment. It is difficult to access the acceptability or dry or wet layups on the phone.

BUILDER HINTS - LONG-EZ AND VARIEZE

Do not use peel ply over the entire structure. This starves epoxy from lower foam surface, makes inspection difficult, gives an erroneous impression of good surface smoothness, makes it easy to unknowingly damage structure during finishing and adds weight. For example - if the elevators are peel-plied they will be too heavy to balance and must be discarded. Do peel ply surface edges of glass plys whenever they exist and, of course, whenever a layup will be later made over a cured surface.

Cockpit Paint - We have received a number of questions regarding ultraviolet protection of the glass structure inside the cockpit. Cockpit structure, like the external structure should never be exposed to direct sunlight without the protection of a suitable ultra violet barrier. A well maintained coat of color paint is adequate, but it is desirable to use primer over the fiberglass surface. Dupont type 70S provides the best UV barrier (high content of carbon-black), however type 100S will result in better adhesion to enamel paints. Mike and Sally used a Standard Paints product, called "Zoletone", Charcoal Gray in their cockpit. This material gives a beautiful spackle-type finish that hides minor irregularities and the glass cloth weave. This paint was sprayed directly on to the glass interior, after scuff sanding with no filling at 70 lbs. per square inch pressure.

Engine mount and mount extrusions - The older conical-type engine mount had tubes that were flexible enough to accommodate minor variances in the positioning of the aluminum angle extrusions in the fuselage. The new mount designed for the Lycoming dynafocal configuration has extra supports and is very rigid. Extreme care was taken to make the Brock welded mount accurate, to fit the extrusions, however normal tolerances may preclude a good fit on all airplanes. Thus, we are recommending the following method to assure an acceptable fit: Before allowing the extrusions to cure in place in the fuselage, clamp the welded mount to them. Shim with additional plies of BID if needed on the fuselage and centersection spar. Let the extrusions cure with the welded mount clamped in place.

Hot wire troughs - Use the following method to separately cut the troughs. This gives more accurate, sharper cuts. Nail a temporary template (a popsicle stick works fine) to guide the wire straight across over the trough. Then, remove the stick, and in a separate pass, cut the trough. Be careful to not let your core move between the cuts. **SKETCH OMITTED**

Drill a sight hole through all control push rods in order to verify that you have the rod ends screwed in with sufficient threads into the push rods. This hole should be 1/16" diameter, located at 0.4" from the end of the push rod. **SKETCH OMITTED**

Page 9-3, Long-EZ plans, a small 1/8" o.d. brass tube 1/2" long is called out to be used in the end of the Nylaflow brake line. In some cases the little brass tube will slip up into the Nylaflow tube, and be difficult to extract. This problem can easily be overcome by using a Weatherhead tube, part #2030X4. This little tube has a flange on it and it works great. If you cannot obtain it locally, Aircraft Spruce has them.

CP27, page 5

Wiring the Rochester fuel pressure gauge.
Mike used Rochester gauges on his Long and they work well. The oil pressure and oil temp. gauges were straight forward to wire. However the fuel pressure gauge is a little different and some builders may not have received a wiring diagram. **SKETCH OMITTED**

We put a Marvel Shevler MA3-spa carburetor on N79RA without a primer system and since have accumulated over 350 hours on the airplane. The MA3-spa carb has a built in accelerator pump which really makes starting the engine a lot easier, particularly in cold weather. If you plan on operating your 0-235 Lycoming in cold climates, an accelerator pump or primer should be considered almost mandatory.

After you have installed your ailerons, check to be sure you have a minimum of 0.1" gap between the aileron leading edge and the bottom skin of the wing. This is necessary for protection from ice freezing the aileron to the wing. This can happen even in VMC conditions, if the wing is wet and you climb above freezing level so do be certain to comply with this.

Long-EZ builder hints.

Heavy Unidirectional Fiberglass Tape - The 3" wide roll of unidirectional glass is used only for the spar caps of the wing and centersection spar. "BID tapes" called out are cut from BID cloth (generally 45 degree orientation). Other UND pieces or strips are cut from UND cloth. Be sure fiber orientation is correct.

The canard inserts (page 10-2) should be drilled to match the hole pattern of CLT (page 10-3). These inserts (CLI) are available from Brock. Brock is also stocking the NG5 plate (page 13-3).
Note: The raw materials list does not include the 1/8" aluminum for these parts.

Aft fuselage side shape. A number of builders have noted that the A-5 drawing has a different shape the that obtained when fabricating the fuselage sides per the page 5-1 dimensions. This approximately 0.2" error will not present a problem if you follow these instructions: Carefully follow all the dimensions on page 5-1. This will assure that the firewall will fit. Do use the 5.8 and 6.9 dimensions on A-5 and be sure the extrusions are perpendicular to the top longeron. Ignore the small difference between the bottom shape and that on A-5.

Long-EZ Cowl and Canopy fitting.
As will be shown in the new Long-EZ Lycoming engine installation section (IIL), the Lycoming cowl has been moved aft 0.7" from where it was in a VariEze. This was done to provide better clearances. With the new dynafocal engine mount, the engine is moved aft also, to provide good magneto clearances and an acceptable structural arrangement for the mount tubes. The new Section IIL will show you how to fill the cowl-firewall gap when mounting the cowl using the method used on N79RA and on Mike and Sally's Long. Cowling manufactured for Long-EZs after December 20, 1980 have the lip extended to allow easier installation. These cowlings can be identified by checking the dimension shown below.

SKETCH OMITTED

(OLD COWL=32.0)
(NEW COWL=32.7)

This cowling move has resulted in a miss-match of cowl-to-firewall at the top of about 0.2". Mike faired the miss-match in with dry micro, since he had already fabricated the canopy aft cover piece (Chapter 18). To avoid this micro fill, we suggest that you: Trial fit your cowling to the firewall before carving your canopy aft cover piece. If you have not cut out your firewall, make it taller at the top and trim to fit your cowl during Chapter 18. (see LCP #48).

VariEze builder hints.

Under the thigh support, in the front seat on the right side, there will be a gap under the right console, which could possibly allow a small object stored under the thigh support to slip under the console into the area near the pitch control belcrank. This "gap" should be closed off. 1 ply of BID will do it.

We have talked to several builders lately building from 2nd Edition of the plans who have not been reading Chapter 26 (plans updates). Do update your plans with Chapter 26 and all applicable newsletters before continuing construction.

ACCIDENTS

The CP Newsletter reports accidents and discussed their conditions and causes for information purposes for all operators. We have always investigated accidents in the interest of determining information that we can disseminate to you to prevent recurrence. It should be recognized in our discussion of accident conditions or causes that

generally this information is preliminary since it is published before the availability of the FAA accident report.

A Tennessee VariEze crashed, fatally injuring the pilot and passenger. The aircraft was observed making a low pass by his house when the aircraft hit a tree and crashed. The pilot had a reputation for this type of flying and had been warned by others in the past but to no avail. The accident was late in the afternoon and the fact that the pull out from a steep dive was into the sun could have been a factor in the pilot's inability to judge the pull out angle. No malfunction of any part of the aircraft could be found. This flight was clearly in violation of FAR minimum altitude criteria.

PLANS CHANGES

We at RAF, or course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas, FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify this aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LONG-EZ PLANS CHANGES

LPC #42 OPT Page 4-2

Add "alternate the BID and UND plies that reinforce the sides of the forward face of F-22". Note: Modification is not required if you have already installed these without alternating.

LPC #43 MEO Page 18-7
Lower right "to firewall bulkhead" should be "to aft end of canopy frame FS 117" (two places). See page 18-5.

LPC #44 MEO Page 10-1 Step 1 paragraph two
Refers to two 7 x 14 x 41 blocks (two places), change this to one block.

LPC #45 OPT Page 9-3
Move the 3/8" holes in all four extrusions up 0.4". Also modify outlines to maintain original edge distances around the 3/8" hole. This moves the entire main gear up 0.4", resulting in an improved gear-fuselage juncture reducing aerodynamic drag.

LPC #46 OPT
Revise F28 bulkhead by moving the longeron notch down 0.25". This raises F28, for better fit to canopy.

LPC #47 DES
Due to a probable rubbing of the rudder cable on the aileron pushrod, the left hand rudder pulley bracket should be moved up 0.6". If you have already mounted the 3 bolts in the firewall such that you cannot make this change, you can provide cable clearance by carefully bending the rudder pulley bracket to move the pulley aft approximately 0.2". Bend as shown below. **SKETCH OMITTED**

LPC #48 DES, Firewall, page A4
Increase size of firewall at top as shown to assure adequate height to fit cowling. **SKETCH OMITTED**

LPC #49 MEO Page 22-6
On circuit breakers, change "roll trim" to "fuel pump".

LPC #50 MEO Page 7-1
Section A-A. This sketch is not accurate. See page A2 for the correct full size drawing. Also note LPC #46 in this CP.

LPC #51 MEO Page 10-1, Step 1
Refers to Chapter 13 for winglets, should be Chapter 20.

LPC #52 MEO Page 8-1
Roll over structure assembly 4.5" should be 4.0", moving shoulder harness insert outboard 1/2".

LPC #53 MEO Page 2-1
Add CLI and NG5 to Brock list.

EZ CALC

The development of the fuel flow calculator is still underway but delayed somewhat due to parts availability. We expect to be testing a mock up unit in our airplane this month. We will also evaluate a new turbine fuel flow transducer in a gravity flow system to determine if

it can be used in a standard VariEze. The dimensions are 3" x 6" x 1.5" mounted vertical and the unit will be detachable or can be flush mounted. See CP #24-7 and 26-6 for more complete details.

More foam substitutes - CP #26 listed a high density (18 lbs. per cubic foot) white urethane foam as an allowable substitute for the 16 lbs per cubic foot R250 PV foam previously listed for the VariEze and Long-EZ. We are now listing a medium-density Clark white urethane foam as an allowable substitute for the 6 lbs. per cubic foot PV R100 (light red) foam. See the table below. The distributors may be suppling either type for a temporary period. We have no plans for any substitution of the PV R45 dark blue foam in the Long-EZ list. Its superior peel strength and damage resistance justify its higher cost.

VariEze
Old Specifications
R100 6 lbs. per cubic foot (light red)
2 pcs. - 90cm x 80cm x 9mm
New allowable substitute
6 lbs. per cubic foot Clark (white)
3 pc. - 3/8" x 24" x 48"

Old Specifications
6 lbs. per cubic foot (light red)
2 pcs. - 90cm x 30cm x 9mm
New allowable substitute
6 lbs. per cubic foot Clark (white)
1 pc. - 3/8" x 24" x 48"

Old Specifications
6 lbs. per cubic foot (light red)
1 pc. - 15cm x 27cm x 25mm
New allowable substitute
6 lbs. per cubic foot Clark (white)
1 pc. - 1" x 6" x 12"

Long-EZ
Old Specifications
R100 6 lbs. per cubic foot (light red)
1 pc. - 1" x 6" x 10"
New allowable substitute
6 lbs. per cubic foot Clark (white)
1 pc. - 1" x 6" x 12"

Old Specifications
6 lbs. per cubic foot R100 (light red)
2pcs. - 0.25" x 35" x 44"
New allowable substitute
6 lbs. per cubic foot Clark (white)
3 pcs. - 1/4" x 24" x 48"

SHOPPING

Aircraft Spruce and Wicks stock a safety kit which includes:

50 gloves
1 pair goggles
12 dust masks
1 can hand cleaner.

The kit costs approximately $25.00 and we have found them to be most useful.

Aircraft Spruce would like to request that overseas customers order all finishing materials that they may require (featherfill, primer, surfacer etc.) with their initial order, so that all of it may be shipped by surface vessel. Flammable materials cannot be shipped by air due to regulations. So if you wait until you need finishing materials, you will not be able to get them very quickly, as they will have to go by surface vessel.

Both Aircraft Spruce and Wicks will have the 3.40 x 5 wheel pants in stock in February. These are suitable for both VariEze and Long-EZ. They will also be stocking wheel pants for 500 x 5 tires (Long-EZ). Contact them for expected date.

Ken Brock Manufacturing catalogs are $3.00 and this is not refundable with an order. Catalogs cannot be sent out C.O.D.

Ken Brock is now manufacturing the heavy 1/4" aluminum main gear mounting extrusions. They incorporate the 0.4" move (plans change #45) and also have 1/2" diameter flanged steel inserts for improved durability. Part numbers are - Aft: LMGB-RA and LMGB-LA, Fwd: LMGB-RF and LMGB-LF. The forward parts are supplied without the large lightening holes, so VariEze builders can saw off the top 1" to install a Long-EZ gear on a VariEze.

PRICE INCREASE ON GEAR.

Due to increases in materials and labor costs we are having to increase the price of the S-glass parts. Effective 1 February 1981 the new prices are:

NG-1 $309.00
MG-1 $ 55.55

Backlog on these parts is approximately 9 weeks. Main gear are shipped Greyhound, freight collect. Nose gear are shipped UPS. Please be sure to include your phone number with orders.

Video tape of Moldless Composite Construction

RAF had a crude preliminary version of an educational video tape on glass/foam construction at the booth last year at Oshkosh. Many have asked for copies of the tape when it has been shown at our weekly Saturday demonstrations. We have investigated the cost of producing an improved version for sale in the 1/2" home video formats of VHS and Beta II. We currently plan to have the tapes available by late February, contact us at that time for prices.

VARIVIGGEN NEWS

Wayne Wilkins reports good progress on his Viggen 12VV. He sent in a bunch of photos and has his main gear and nose gear installed per N27MS, and is happy with it. It looks excellent in the photos. Wayne's Viggen is skinned on the bottom and is on the gear.

Ken Winter, Tulsa OK. is working on composite SP outboard wings. Inboard section is basically complete. Ken may be the next Viggen to fly.

Orvill Winfield also has the N27MS main and nose gear and his looks great in the photos. His Viggen is upside down on saw horses and he is skinning the bottom.

Arthur Schwartz' Viggen now has 16 hours on it and Arthur is very pleased with it. The problems we reported in CP 26 page 9, have been corrected and Arthur reports that his Viggen is hands off now and he really is enthusiastic about it. N27MS is flown here at Mojave about every Saturday but since returning from Oshkosh, has not been on any trips, she now has 480 hours.

RAF MODEL 58 PREDATOR UNVEILED

We are using this newsletter to announce a development program that has been underway at RAF since late 1978 on a new agricultural aircraft. The design came out of a feasibility study done by RAF for Mr. David Record. The requirement was for an efficient, high-capacity aircraft using the PT-6-34 turboprop engine. The span had to be long for maximum swath width. Stall/spin resistance, visibility and pilot crash protection were also prime considerations.

After evaluating several configurations, a connected-tandem wing arrangement was judged best for the requirement. This arrangement allows a long span and provides low induced drag. The chemical hopper at the cg does not interfere with wing structure. The pilot's position in the large vertical fin allows improved protection and visibility. The elevators, on the inboard forward wing provide pitch and 'direct-lift' control for improved ground-proximity flying qualities. Differential ailerons on the outboard wing provide roll and proverse yaw without a pitch trim change. There are no controls on the aft wing. The inclined bracing of the wings allows an extreme span without excessive structural weight.

The RAF Model 58 will have satisfactory climb performance at its gross weight of 12,300 lbs. (6,700 lbs. in the hopper) in a 1.5-g turn. Current ag aircraft using the same engine have marginal turn performance using only 4,200 lb. payloads. Maximum L/D for the Predator is over twice that of current ag aircraft. Combining advantages of payload, speed, swath width, turn performance, ferry speed and fuel flow, results in a productivity of greater than twice that of current ag aircraft.

The concept of joining tandem wings is not a new one. It was originated in the 20's by Norman Warren and Rex Young of England. Wind tunnel tests were later done by Darroll Stinton and Warren using the concepts earlier proposed. More recently, Dr. Julian Wolkovitch, an aerodynamist from California, used joined wings on a recreational glider prototype. He has proposed several configurations of wing

joining, to make maximum use of the structural benefits of the bracing achieved with large dihedral angles. The Rutan-designed Predator Model 58 has undergone extensive wind-tunnel tests conducted by NASA's dynamic stability branch at Langley, VA. Those test are directed by Joe Chambers and Joe Johnson who have had the foresight to keep alive an aging 12 foot wind tunnel to investigate many interesting aerodynamic theories and configurations. The wind-tunnel test (see photos elsewhere in this newsletter) program has solved several stability deficiencies and confirmed the performance of the Predator configuration.

Details of the development plans for Predator cannot be released at this time. When an announcement can be made it will be in the Canard Pusher.

IMPORTANT! WRITE RAF IF YOU HAVE A RAF-DESIGN FLYING

The following paragraph was printed in CP #25, but we have had a poor turnout of letters from the owners. This list and the CP newsletter is our only means of notification of safety bulletins. If you have an airplane that has flown, please scan the list below then drop us a card or letter with the needed information. Also, if you have not already done so, please send a photo of your aircraft to the Historian of the International VariEze Hospitality Club, Irene Rutan, 8526 Calmada, Whittier, CA 90605.

RAF maintains a list of completed EZ's so we can contact you direct in the event of a flight-safety-related problem requiring an emergency directive. This list is also beneficial to access statistical items relating to structural and systems reliability. The list is, of course, kept in confidence. A printout of registration numbers is shown below. We believe there are about 100 flying VariEzes that are not on our current list. If you have an EZ flying please scan this list to find your number. If you are on the list please write RAF and tell us the date of first flight and the current total flight hours. If you are not on the list please write and supply:

1. Type - (Long-EZ, VariEze, VariViggen)
2. Name of Owner
3. Address
4. Date of first flight
5. Registration number (N-number)
6. Total hours

Comments from Jud Bock - "I have installed the Long-EZ nose and main gear on my VariEze so I am sure I will have a lot better landing gear system, but it is making me even more overweight than I already was. I decided the best thing to do about it was to lose 30 excess pounds off of my 230 lb body, which I have almost accomplished. Also my wife has lost nearly 20 lbs, so the 17 or 18 extra lbs I picked up on the bird is more than compensated for by the 50 lb weight loss of my wife and myself. I attend Weight Watchers and you can rest assured I am the only one in the class who isn't losing weight because of a woman or a man. My white, red and blue mistress has put on weight, so in order to be compatible with her, I had to lose or else become a single place pilot".

Fuel venting - Long-EZ
The Long-EZ fuel vent lines in the wing are positioned so their inlets are above the fuel level in level flight or climb. Thus air expansion with altitude increase is expelled out the vents with no fuel loss. However, when parked nose down with a large fuel load, the vent inlets are submerged. If the fuel caps were perfectly sealed, expansion on the ground due to rising air temperature could force some fuel out the vents. The fuel caps used in the Long-EZ do not provide an air-tight seal around the dzuz-head. Thus, this parked fuel loss will not occur. If you install a tightly sealed cap, like those on Mike and Sally's Long, consideration must be given to expansion. A tiny hole in the fuel cap will do, or you can install a second vent line with it's inlet at the far aft inboard top of the tank. This vent must be routed to the same outside location and orientation (into the airflow) as the other vent. We have tested an alternate configuration consisting of a small hole in the existing vent line where it enters the tank, however this configuration results in fuel loss in climb.

FLIGHT TEST DATA

Capt. Ken Swain of Travis AFB, CA., has recently conducted an extensive set of tests to document the performance of his O-235-F VariEze using his newest-configuration Scmitar prop. Data for his super-performing VariEze are presented below. Of significant note is the passive "constant-speed" action of the prop: full power climb at 80 mph results in 2800 rpm and at maximum speed in level flight (217 mph) rpm is only 2950. This results in a significant improvement in takeoff performance over a conventional prop that lugs the engine down to 2500 rpm at low speeds. Scmitar props have been flying since the 30's. However, they have not had adequate structural reliability. If a reliable full-Scmitar prop can be built, we will see very substantial low-speed performance increases in our high-speed fixed-pitch aeroplanes.

Getting ready for 2nd flight of N26MS.

N12VV - Wayne Wilkins, on the gear.

Mike DeHate, from San Diego has installed this "quiet" exhaust system on his VariEze. It was designed and built by Rudi Kurth, and Mike reports that it is quieter than the standard exhaust system. Anyone interested in this should contact Rudi Kurth, Langgasse 51, CH-3292, Busswil, Switzerland.

In Switzerland, homebuilts have to meet strict noise controls, and Rudi has developed this system on his own VariEze and has over 200 hours on it now.

The following letter was received just at press time for this newsletter. With Victor's permission we are printing it:

Dear Burt and Company,

Thank you for your Christmas card. It found me recovering from a crash landing of my VariEze and with even more respect for the design. On November 11, 1980 I was working to take off the 40 hours a bit at a time. We had about 30 minutes before dark after work (my second mistake) to get a few trips around the patch. Mary-Kate and I had decided to install the new Long-EZ elevator trim but I over-ruled and decided to put it off until certification (my first mistake). I wanted to complete the 8 hours remaining to my certification as soon as I could.

After one touch and go I was climbing out about 600-700 AGL when I eased the stick forward to level off at 800 and nothing happened. The bolt between BC4W10 and CS136 had come off. I immediately called "mayday" and requested emergency equipment. I thought I was dead. However, I realized 62MV was still climbing so I began to analyze my possibilities. I could not reach past my right leg to reach CS136 so I experimented with power changes. I found that at about 80 MPH indicated the nose would begin to drop and about 120 MPH it would pick up. The initial oscillations must have been 200-300 feet up and down. I found by careful throttle changes and by moving my body forward and backward I could greatly reduce the up/down changes, but I still was faced with only gross control. I flew 3 patterns, about 15 minutes, and on the last down wind discovered I could touch the elevator balance weight with my right toe. Holding about 100-110 MPH and using the toe technique to give progressive downward dips I made my final approach to runway 10 (4000' long) into a 5 degree right wind of 5 to 10 knots. At about 30 to 50 feet AGL, darkness made judgement poor, I was almost to the runway when the nose began its upward cycle at about 80 MPH. Knowing I would not stand another cycle, especially the 120 mile per hour dive I cut power and dropped it in. At the same time I cut power I deployed my landing brake, I probably should not have used the landing brake since it does tend to increase the sink rate.

The landing was just about 20 feet short of runway 10 in a slight left turn so that I skidded across the corner of the runway and onto the grass beside the runway. I came to a stop in the newly planted wheat field about 20 feet from the runway. I had lowered the nose gear to take up shock as well as the possibility I could make a controlled landing. The nose gear push rod bolt sheared, the main gear attach taps on the gear sheared or split , and the lower cowl was crushed. The intake spider broke and the carb separated as did the gascolator and intake hose. The oil pan was crushed and the bottom 3" of the firewall cracked and bent aft about 15 degrees. We hit so hard that the pilot's seat area broke and combined with skidding across the runway made a hole clear through the pilot compartment floor about 3" from the left console and about 9" wide by 20" long. I was able to turn everything off, release my harness and climb out. I noticed severe pain in my back so decided to lie down because the ambulance was pulling up. I next woke up in the ambulance on the way to the hospital. I suffered shock and two cracked vertebra #L2 and L3. After 11 days in the hospital and a month at home I am feeling pretty well. I will wear a back brace for at least another month but should not have any future problems.

Why did the nut (MS210042-4) come off? I don't know. I may not have had it on all of the way but I am sure I did because I had developed

the habit of checking for 2-3 threads through the nut. The canard and of course this nut had been off about 10 times for work on the electrical and instrument systems. Do such nuts wear out? The nut and bolt are included for your inspection. I find I can get it on to almost one thread with just my fingers. The FAA inspector was Glenn Martin of Wichita GADO. He was just as surprised as I to find out the a VariEze will fly without elevator control.

N62MV normally trimmed out level with a slight nose down force required. I was able to correct it with the original spring trim system. At the time of this flight I had 2 gal in the fuselage tank and about 7 gal total in the wing tanks. The engine is an A80-8 and the original long canard is installed.

I expect to wait about a year before repairing the plane. What do you think of having the main gear strut and wing attach areas x-rayed? There doesn't appear to be any damage to the wing or canard attach fittings or surrounding areas. Both lower winglets were ripped off, right rudder was destroyed and of course the gear and gear attachment area. The enclosed photos were taken by Glenn Martin. I would like to have them back because they are all I have. Enclosed find SASE.

Thanks again for an outstanding design. If you would want to question me please feel free to call.

Sincerely,

Victor Sullivan

It should be emphasized that an elevator disconnect downstream of the trim system will not necessarily result in the amount of control Victor was able to achieve. Any small inconsistency in elevator shape could result in a very low or very high trim speed. Victor had rejected his original elevators and build new ones to a more accurate shape - he probably could not have survived a control disconnect with the original ones. The new trim system, of course, could have allowed a satisfactory amount of control and safe landing.

We have inspected the bolt and nut and found it is of the proper length and that the locking friction, though reduced from new condition, seems adequate for proper safetying. It appears improbable that it could have been tightened properly. Victor agrees that it may be possible that he was distracted during canard installation and might not have tightened the nut beyond finger tight. Even the most critical items can be overlooked by the most competent mechanic. For example, one VariEze attempted a takeoff without the 2 bolts that hold the canard on - the canard flew off when the pilot pulled the stick back for rotation. Builders should follow the accepted practice of replacing critical locknuts after several repeated installations (discard any fiber-lock nuts after one use). Also, discard any bolt or nut that has any sign of reduced locking friction.

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE
The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE
At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY
The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for

efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to 27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES
Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these

items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

Brief Long-EZ specifications/Performance
Engine Lycoming 0-235 108 hp.

Span	26.3ft
Area	94.1 sq. ft.
Empty Basic	710 lb.
Empty Equipped	750 lb.
Solo Weight	960 lb
Gross Weight	1325 lb
Max Fuel	52 gal.
Cabin L/W/H	100/23/37 in.
Takeoff (solo/gross)	550/830 ft
Climb (solo/gross)	1750/1350 fpm
Cruise 75% 8000 ft	183 mph
Cruise 40% 12000 ft	144 mph
Max range * 75% (solo/2 place)	1370/965 mi
Max range * 40% (solo/2 place)	2010/1430 mi
Ceiling (solo/gross)	27000/22000 ft
Landing dist. (solo/gross)	450/680 ft.

*40-minute reserve

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine

installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 28. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 28. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 28. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 28. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 through 28.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

RAF Activities.

We are pleased to announce that we have entered the Soaring Society of America's contest to design and build a home-buildable single-place, self-launching sailplane. Because of the competitive nature of this event, we regret that we can not release any details concerning configuration, power, performance, or method of construction. There are currently 55 official entries in the SSA's contest, which was announced in September 1980. The fly-off and evaluation of all entries is planned for the summer of 1982. Please do not call or write to us for information on our entry. All information that we feel we can discuss will be released right here in the Canard Pusher. This is also

in line with our policy not to put out information on any project we may be working on until we have flown it successfully.

Saturdays from 11:00 am to about 2:00 pm have been very busy with from 30 to 100 visitors showing up at the shop. Generally we have the VariViggen, the VariEze and two Long-EZs on display. We have been showing the construction video tape plus a very entertaining tape of RAF planes flying formation. We then generally have a "bull session" answering any builder or pilot questions and wind up with flying one or all of the airplanes, at around 1:00 pm.

RAF will be closed and the Saturday demo not given on the following dates:

23 May	Watsonville Fly-in
20 June	Cafe Race 250
1 Aug & 8 Aug	Oshkosh EAA Convention

Video Tape

We recently completed our video tape on construction techniques used in building moldless foam/fiberglass aircraft structures. This video tape should be a valuable tool for the first time builder as well as the experienced builder. It runs for 96 minutes and thoroughly covers every phase of construction including health precautions, foam preparations, hot wiring, foam damage repair, epoxy mixing, the use of micro balloons, flox, fiberglass, both UNI-directional and BI-directional, wing shear webs, wing spars, wing skins, leading and trailing edge treatments, corner tapes, peel ply and much more. This tape is available from RAF for $49.95 in either Beta II or VHS (half inch format).

Newsletter list goes on the Apple. We now need your number !

You've all heard good-news bad-news stories. Well, the good news is that RAF is in the process of putting the growing Canard Pusher subscription list on our Apple computer, which will hopefully make the system, by which you receive your copy every three months, more efficient. In the past the mailing labels have been typed by hand - a tedious task at best. Computer-generated labels will speed up the processing of address changes and renewals. This improved system will benefit you as a subscriber.

Progress is not made without sacrifice, however. We realize that the change over to the computer may not be flawless and ask that you be patient with us during the transitional period. Names go on the computer as we receive new subscriptions or renewals, so it will take a full year to use up all the hand-typed labels and get all subscribers on the system.

The bad news is that in these number-oriented times, we are asking that you keep track of yet another number! Each subscriber will have a unique subscription number which will be the first number in the first line, right after the # sign.(#100 in the example). As in the old system the issue number of the last CP you will receive before your subscription runs out will also be in the first line, only now it will be much more obvious.

#100 Last issue - CP 34.
John Doe,
1234 Main Street.
Anywhere, USA 9999

When you renew, or if you have a question about your subscription, please mention your subscription number, or send in an old label. This will greatly speed the processing of your order.

None of us are thrilled with the prospect of losing our identity and being reduced to a number, so we'll let you in on a secret. We will be able to find you by your name, (as long as the computer hasn't misspelled it!) if your Great Dane eats all of your back issues and you can't remember your number due to the temporary amnesia you incurred while chasing the dog around the house, slipping in the wet epoxy on the floor and hitting your head on the corner of your work bench! This is the only excuse we will accept, however! Our system is small and limited - please help us with this so that we can all benefit from the system and so that RAF can be of better service to our Canard Pusher subscribers.

It has become necessary to further clarify Rutan Aircraft's position in relation to the homebuilder and the support we give. Rutan Aircraft can only offer the assistance that helps them interpret the plans when they desire to build their aircraft like the prototype we have tested. We cannot assist in the design and construction of modifications. We cannot comment on the advisability of modifications. Many of the developments we design and test do not work as predicted. Thus, without testing your idea we cannot reliably predict its success. A similar situation exists for substitutions of materials. We will not be able to advise you on any material we have not tested ourselves.

AD-1 Reaches 60 degree Wing Skew in NASA Flight Tests.

The RAF-designed AD-1 jet research aircraft has successfully completed initial wing-skew-angle envelope expansion flights tests with the wing being skewed to its 60 degree limit. Although the sensitivity, yaw trim change and coupling were noted, flying qualities at full skew were better than anticipated.

The AD-1 airframe and its two TRS-18-046 jet engines have required no repair or unscheduled maintenance during the test program. The 100% availability is unusual for a research aircraft. For further information on the development of the AD-1, see Canard Pushers No 10, 11, 17, 18, 19, 20, and 23.

Video Tape (See Page 1) Add $4.00 for postage and packaging for mail orders. The $49.95 price is for walk-in customers at RAF.

26MS - Mike and Sally's Long.

Currently we have 85 hours on our Long and it is literally running like a Swiss Watch. We are truly delighted with it in every possible way.

We have been using it to commute to work every day for the past couple of months. From Techachapi to Mojave by road is 26 miles, about a 30 minute drive. It takes between 8 and 12 minutes in the Long, depending on the winds. We use two to two and a half gallons for the round trip. This is almost exactly what we use in our Honda Civic car. Besides the time saved the biggest thing is the 'fun' factor. There is a lot of enjoyment in flying across the desert in the early morning with glass smooth air, no traffic and the stereo tape deck playing in the head phones. Coming down-hill in the morning, we usually fly at very low power settings. The quiet, smooth exhilaration really makes it enjoyable to come to work.

All flight tests, engine break in etc., have now been completed. All systems work perfectly. The Radair comm, nav, and transponder work very satisfactorily. The Sigtronics intercom and audio switcher work excellently in conjunction with our stereo tape deck. This also gives us the capability to transmit from either cockpit. The newest piece of equipment recently installed is a Silver Fuelgard. This small instrument accurately reads out fuel flow in gallons per hour and you can look at fuel used with a momentary switch. This fuel flow meter is a TSO'd instrument and uses a flow-scan transducer. We installed it in the fuel line so that all fuel on board runs through it. It is accurate within +- 2 percent. So far it has verified the Owners Manual fuel flow information very closely. N26MS will burn 1.9 gallons per hour at minimum power required for level flight at 8000 ft (max endurance) and at 75 percent at 7/8000 ft it reads 6.7 gph. Take off, full rich at sea level is a shock, 11.7 gph!! On a recent cross-country, we went to Northern California, a straight line distance of 404 nm (471 sm). On the trip up north we had a ferocious head wind of 29 kt (33 mph) so we ran at approximately 70 percent power at 8500 ft for a fuel flow of 6.4 gph. This gave us a ground speed of 130 kts (150 mph) with a true airspeed of 159 kts (183 mph). Our time enroute was 3.1 hours and we used right at 20 gallons of gas. By contrast on the return trip we had a tail wind!! We climbed to 11,500 ft, where the tail wind component was 35 kts (40 mph). It took some will power, but we pulled the power back to approximately 48 percent which gave us a fuel flow of 4.4 gph, and a true airspeed of 133 kts (153 mph) which, with the tail wind, had us crossing the ground at 168 kts (193 mph). The time enroute was 2.4 hours and we burned a total of 10.6 gallons of gas! I honestly believe that a Long-EZ built to the plans will consistently give these kind of results. The airplane is incredibly comfortable, reasonably quiet, particularly with David Clark headsets, and is an honest to goodness, economical, high speed touring machine, with good baggage capacity, excellent high altitude capability and unbelievable range. All in all, looking back at the intensive effort required to build it, it was well worth it!! The Long continues to delight us, Sally takes it to her 99's meetings, I have been into terminal control areas, we have flown it quite extensively at night. We have flown over mountains, over ocean (to Santa Catalina) and it is just super. The Lycoming O-235-L2C has continued to run like a dream and to be honest, I have no regrets. If I had to do it again, I would build it exactly as we did, using the same engine. The only thing I would not recommend is the electrical system we have. The engine came with a 28 volt starter and alternator, and all the electrics on the airplane are 12 volt. We have got it working, but it was simply too much hassle for the average builder to have to put up with, when you

don't have to. N26MS will be here at RAF on a daily basis, and we plan on attending most of the flyins, including Watsonville and Oshkosh.

Long-EZ #4 by Dick Rutan.

Last summer Mike Melvill and myself decided to build ourselves one-each Long-EZ. We agreed to work together on the basic structure then split off and finish individually. On 15 June 1980 we started and with a lot of help from Mike's wife Sally and my friend Jeana Yeager both aircraft are now flying. Mike's (N26MS) late December 1980 and mine (N169SH) in early April 1981.

Mine took longer to build for two reasons. First, Mike worked harder, but the biggest reason is all the changes I made to mine. I thought I wanted more power, more roll rate, more negative g and IFR equipment. I installed a bigger engine, longer ailerons, different canard airfoil and several other changes. All these mods took more time to build, cost more and after first flight, I found they didn't work. When I should have been very happy after it flew I was not. Instead of having an aircraft I could use I found I had a "prototype" that needed work. The big engine over-heated, the revised canard airfoil resulted in loss of speed-stability at high speed, and very poor stall characteristics (a nose drop). The standard Long-EZ rolls about as fast as mine and because of a poor prop match, Burt's Long even out-ran me on the first flight! I was then faced with finding fixes for all the problems.

I'll fix the problems but it will take some time and effort. But in retrospect, I wish I had stayed more standard. My airplane now is a compromise, a whole bunch more effort that I feel is not worth it.

If you see my light-blue modified Long-EZ (N169SH) at flyins and airshows, remember the mods were not approved by Burt or RAF. In fact Burt was not aware of most of them. Please don't bother RAF about my mods. They have enough to do just to support those building from the basic plans. I do not intend to do as complete a test program on my airplane as RAF did on N79RA. Thus, they are in no position to verify or recommend my modifications.

I am now deeply involved in the Voyager round-the-world program and will not be able to get involved in any way assisting builders.

I don't recommend any of the changes I've made and wish I had not. The best advice I can give is to keep it stock, build it light, and resist the temptation to change, especially anything structurally.

Sun-n-Fun Flyin.

Although none of us from RAF were able to make it over to Sun-n-Fun, RAF was very well represented by Irene Rutan (Burt's Mom) with excellent help from Johnny Murphy. Irene recorded 24 VariEzes and 1 Long-EZ that landed at Sun-n-Fun during the week up til Friday, when Irene had to leave. Here is a list of pilots and their airplane "N" numbers:

Johnny Murphy	Long-EZ	N21VE
Tom Bradford	VariEze	N25TB
S.E. Cochran	"	N115AM
Dick Cutler	"	N46RC
Norm Dovey	"	N16ND
Frank Dudley	"	N20VE
Mule Ferguson	"	N2286A
Tim Gehres/Steve Wood	"	N56EZ
Dave Hesterlee	"	N86DH
Larry Hoepfinger	"	N7AH
Gerry Mason	"	N27GM
David Richter	"	N877EZ
Ray Richards	"	N48EZ
Robert Ridihalgh	"	N25RR
Ed Rockwell	"	N7ER
Jack Sargent	"	N75EZ
George Scott	"	N240EZ
Earl Thompson	"	N55EF
Jim Trombino	"	N46JT
L. Uhley/P. Mason	"	N2UN
Joe Walker	"	N419JW
Fred Wimberly	"	N99FW
Bob Woodall	"	N301RW
Don Yoakam	"	M77DY
David Langston	"	N83DL

VariEzes made the front page of the St. Petersburg Times twice during the week. The VariEze race was held over a 49 mile course on Friday morning, and on Friday night the whole group got together to swap tall stories. Irene reports that VariEze pilots/builders are the finest people in the country and she was proud to see so many beautiful ships flown in for the folks to see. She wants to thank all those who were there for being so good to her and showing her such a great time. She loved every minute of the week.

Tim Gehres sent us the results of the race, held on Friday. Ten people entered and 8 raced. The race was a handicap race, based on the Owners Manual performance, baseline being a VariEze with an O-200 with wheel pants and a spinner. Congratulations to Paul Mason who won (his corrected speed for the race was 182.23 mph). George Scott was second at 170.77 mph and Bob Woodall was third at 169.54 mph. Johnny Murphy flew his Long-EZ in the race, although he was not an official entry and surprisingly his speed would have placed him second at 177.10 mph (good show Johnny!). Tim Gehres also was not an official entry and his speed was a blazing 183.9 mph! We would like to thank Tim Gehres and Steve Wood for the work they put in in organizing and running such a successful race. Hopefully this can become a traditional event each year.

Memories of Sun 'N' Fun - 1981
by the "Real" George Scott.

1. Dave Hesterlees VariEze rising through the North Georgia haze as he departs Bear Creek airport right on schedule to wing into formation with us on the way to Lakeland.

2. The chatter of the ground controller at Gainesville Florida wanting all the performance specs on the EZs.

3. Rapid fire direction from the tower controller at Lakeland. He says "Don't talk to me, I'll talk to you" and then proceeds to ask if we want to make a 360 degree turn behind the STOL or what?

4. As we taxi through the Warbird parking area all thoughts of the spectators leave WW II and join Star Wars.

5. The envy of all, as Johnny Murphy comes winging in via his Long-EZ "Sweet Music".

6. How Eze the tie down stakes go into the Florida sand, compared to the Oshkosh black soil.

7. Yes, they still ask "Where is the tail wheel?" "What's the solar panel for" and "Where's Rutan".

8. Tim Gehres and Steve Wood trying to coordinate their work schedules, commute from Orlando and still organize the VariEze Race.

9. Paul Mason calling every day with excuses as to why he couldn't run the race but winning anyway.

10. Dave Richter on a nationwide tour from New Jersey to Lakeland, to the Islands, to the West Coast, to Alaska, to Oshkosh and beyond. (Dave, are "C" rations any better than they were 25 years ago?)

11. At the IVHC banquet a couple of local patrons ask, "What's a VariEze?" and 12 people all explaining at once.

12. Irene Rutan traveling all the way from the West Coast and spending all week logging in VariEzes and helping to pass the word on RAF.

13. Jeff Rose smiling when he explains the comparison of flying the VariEze, the Long-EZ and the Defiant. (How many of us have accomplished that?).

14. My sweet little wife working two days parking big ole airplanes and how proud she is of the volunteer patch she's earned.

15. Mule Ferguson scaring the devil out of the spectators with his ugly green mask.

16. VariEze pilots sneaking a peek at the canard ultralite "Goldwing" (Don't tell Burt!).

17. How the tower Controller's voice changes with a little respect when he recognizes a real VariEze in the pattern.

18. We vow to install cabin heat in the Long-EZ when the OAT indicates 20 degrees F at 5500 ft and my toes chatter against the rudder pedals.

19. John T. Baugh's pet monkey visiting the VariEze crowd.

20. The strong Lakeland winds blowing from the West seemed to carry a faint odor of Safe-T-Poxy. Could those winds have carried a hint of RAF's latest project?

A note from EZ Ed - owner of one of the highest time VariEzes.

Burt asked me to jot a note for the newsletter since at this writing (4/22/81) I have 680 hours on 777EJ. It first flew in March of '78 and since that time we have really flown it quite regularly. In '78 we went to Oshkosh plus explored all of California twice. In '79 we made a trip through Canada, we were going to Alaska but "someone" got carb ice and Joanne had a tooth go bad in Calagary. In 1980 we went to Montana (home again) and toured some in that area. We also made the Bahamas trip in '80-81 to cap off '80 and start '81. At Easter we went to Loreto Baja Sur, Mexico. Had a really great time.

The reason that the hours build up on 777EJ so fast is that I also use the airplane in my work. I work for Placers Savings and we have 22 branches. I visit each branch at least once a month and often more frequently. I average flying to a branch once or twice a week, (the boss buys the gas) so we really get to keep the cobwebs off Echo Juliet.

As far as maintenance goes I really haven't had any major problems. The engine has run great but I did a top at 400 hours and had one wierdo, a warped intake valve seat. Those two problems though didn't stop the flying for long.

I have used a lot of brake pads as the airplane is an all brake situation after it's on the ground. I can touch down say at 75 mph on a 5200 ft runway, (I did it at Mendocino, with a passenger) and probably would go off the other end. That's with speed brake down and rudders extended. If I ever suspected I didn't have brakes I would land nose gear up. A 2" x 3" x 1/4" steel pad is good for at least 3 nose gear up landings!

When we get 1000 hours we will write another article.

Ed Hamlin.

New Book Details Rutan and RAF Evolution.

A new Tab publication (TAB books, Blue Ridge Summit, Pa, 17214) written by Don and Julia Downie, titled "Complete Guide to Rutan Homebuilt Aircraft" is now available. It is the result of several months of research by the Downies. While much of the book consists of previously published information, the reader who is curious about the early years of Burt Rutan's aircraft work will find extensive information never before written. Also the book is profusely illustrated with over 100 photos.

Care of Composite Structures

Composite aircraft such as the VariEze and Long-EZ should have a virtually unlimited life, provided they are reasonably well taken care of. In addition to normal maintenance as required for the systems, oil and grease where required, etc., it is very important to immediately repair any dings, chips or scratches in the paint/skin as well as the cockpit interior. Any scratches or chips that expose the epoxy/glass structure are subject to immediate ultra violet degradation and/or water absorption, depending on the degree of damage. Skin damage that exposes the epoxy/glass structure can result in water being absorbed into the laminate, and then when the water freezes (expands) there is a possibility of local delamination damage.

To sum up, all hangar rash, scratches, chips etc., in the finish should be repaired and repainted as soon as possible.

Safety-T-Poxy and Humidity.

Good news! The manufacturer of Safe-T-Poxy has confirmed that this type of epoxy can be used in up to 90 percent humidity with no problem. This will be a big help to those of you who live in areas with high humidity. Of course temperature is still very important and although it is possible to make a satisfactory layup in temperatures as low as 65 degrees F, and as high as 100 degrees F., the ideal temperature is 75 to 85 degrees F. Safe-T-Poxy is relatively insensitive to moisture and that is why it can be used in an environment with high humidity. This also a tremendous advantage over the life of your airframe, since the cured laminate is also more immune to water absorption than normal epoxies. This reduces the possibilities of weight gain through water absorption, a common problem with most epoxy laminating systems.

Caution. We have been approached lately by builders wanting to use Ciba Araldite 506/507 epoxy to build their Long-EZ or VariEze. We cannot recommend the use of this material. The heat distortion point of this laminating system is low and can cause long term "creep" problems. The water absorption is high, which will hurt the life expectancy of the airframe. The chemical make up of this material is such that many builders will become sensitized due to high irritation factor.

Remember, Rutan Aircraft Factory, Inc., has spent many thousands of hours, building, testing and flight testing the prototype aircraft that we sell plans for. For us to recommend any material that we have not tested in an aircraft that we are currently flying would be unethical. We have learned that another plans distributor has shifted their recommendation to a cheaper epoxy even though their prototype is not build from the cheaper material. This practice is, in effect, asking homebuilders to test something new to see if it is adequate. This practice is acceptable because each homebuilder is the manufacturer of his own aircraft. However, we feel that ethics require that if a homebuilder is breaking new ground he should be notified that he is being recommended to use something that has not been tested on a prototype.

VariEze stall Characteristics and CG Position.

We recently received a letter from Shirl Dickey of Utah, notifying us of his initial flight tests of his new EZ, N60SD. His letter is printed below:

Dear Burt,
I just wanted to drop you a note telling you of the first flight of VariEze N60SD. My bird is equipped with an O-200 Continental, wing cuffs, speed brake, full instrumentation and a Cessna alternator. I am planning on installing a lightweight alternator.

Sunday morning 2/22/81 was clear, calm and cold, a perfect day for taxi and flight tests. Bruce Tuttle flew his VariEze N95BC down from Ogden and was on hand for help with initial setup and check out of my new bird. Another builder John Wall was also very helpful.

Bruce and I discussed the procedure I would be going through starting with low speed taxi tests, high speed taxi tests and runway flight. All went per plan until I attempted my first runway flight. I had accelerated to 80 mph and pulled the power off and with pitch up command it lifted off and went unexpectedly to 50 feet. I could see that I would not want to attempt a landing on the remaining runway and so after only a slight period of indecision I added power and climbed out.

That first lift off and flight came somewhat unexpectedly and I was immediately filled with apprehension about landing. This was where all my practice in a Cessna 172 and Mooney 231 would have to pay off. I brought it around the pattern at 100 mph on downwind, 90 mph on base and 80 mph on final. I approached low with slight power and crossed the numbers with the runway visible over the nose. Then I chopped all power and it sank unexpectedly fast and my reaction was to pull up elevator, which wiped out my view of the runway and I found myself feeling for it for a nose high landing. Not too graceful but I got it down on the mains and then dropped it on the nose pretty hard.

The roll out was exhilarating. It was the first opportunity that I had to think about what had just happened. We checked the plane out for landing damage (none) and then it was off again. All in all the first flights were so successful that I logged 6.1 hours that day including about one hour flown by Bruce, and some formation flights alongside his Eze. My wife, Diane rode with him and took some air to air pictures. I also flew some long orbits within my restriction area getting the feel of the plane.

No slow flight was attempted but I did investigate high cruise. I got 160 mph indicated at 8000 ft. straight and level which trued out at 181 mph (no wheel pants, no spinner and no nose gear covers) at 2800 rpm.

The only flight problem was a slight left baking tendency. It flew ball-centered with no yaw trim. Roll rate was fantastic, with the rudders it was really quick. Stick forces were roughly equivalent for pitch and roll and very comfortable.

I ended up the day doing touch and go's, working on my technique, I found that it was best to carry a slight amount of power and fly it onto the runway, a Cessna-style flare always resulted in a nose-high, high sink rate landing and so I soon learned not to do it that way. As

the sun was dropping low I reluctantly had to call it a big day and put my new toy away.

The aircraft is everything I had dreamed of and more. It made the 23 months construction period seem like nothing compared to the pay off in fantastic performance and pride of building and flying my own airplane.

Thank you is just not enough to say to you for providing this fantastic design for me and others who have a little ambition and a big dream.

I hope to fly off the restrictions in about a month and one of my first cross country flights will be to Mojave to show you the plane and thank you in person.

Thanks again and I'll be seeing you soon.

Shirl Dickey.

CP28, Page 4

Shirl's initial stall tests were done with nose-ballast as required to bring the cg into the center of the first flight box. Stall characteristics were correct - a stable trim at full-aft stick. He then removed his note ballast which resulted in a cg of approximately 101, about 1 inch forward of the aft limit. The stall characteristics at that cg were not desirable. He reported that an excessive angle-of-attack could be reached using only a few degrees of elevator travel, and the aircraft would roll-off on the right wing before full-aft-stick was reached, particularly when stalled at low power.

When he reported these characteristics to us we asked him to recheck cg because those characteristics normally occur only when the cg is aft of the aft limit. We also asked him to check the contours of his wings for any inconsistency that could cause premature stalling. He did, and was unable to find anything wrong. Shirl and Diane flew into Mojave last week on their first long trip in their new VariEze. Dick and Mike flew it, evaluating the entire flight envelope. N60SD is an excellent flying machine with good roll rate and control harmony. It's stall characteristics, however, are not how a VariEze should be. Instead of the stable trim condition normally obtained at full-aft-stick, N60SD behaved as it wanted to drop a wing unless the pilot carefully controlled ailerons and rudder. Also, the nose seemed to trim to a higher angle than the prototype, N4EZ.

Remembering that these were the characteristics that existed with N4EZ when it was tested at a cg aft of the aft limit, we were convinced that Shirl had done his weight and balance incorrectly. So, we rolled out the platform scales and lifted N60SD onto them. The mystery, however, still existed when the numbers were all calculated - we obtained the same cg that Shirl had reported. We measured the planform dimensions and confirmed that his airplane seemed to be built accurately. It must be that his airplane does have some difference in incidence or contour of the wing or canard, however, we did not determine this.

When Shirl and Diane left, all we could tell them was to go ahead and install 12 lbs of permanent ballast in front of the battery to keep the

cg forward of station 100, thus resulting in the desirable stall characteristics that VariEzes should have.

The purpose of telling you this story is to reiterate to all builders that they cannot assume that each airplane is identical to our prototype. We have learned that variations are to be expected, since these airplanes do not come out of one mold in one factory. Thus each manufacturer should start his test program at the most conservative condition (center of first-flight box cg, for example). Then, as described in the Owners Manual, open the envelope slowly, carefully and safely. Place the limits on your individual aircraft where they properly belong, rather than assume they will be identical to the limits used for N4EZ.

Leaning for Cruise.

Few Pilots realize the extent of fuel economy benefits available when an engine is leaned to proper "best economy" (BE) settings. Due to cooling requirements, BE setting (50 degrees F on lean side of peak EGT) is allowed only below 65 percent power. Lycoming-supplied data shows that a BE, specific fuel consumption is 14 percent lower that at "Best Power" leaning (approximately 90 degrees F on rich side of peak EGT). A pilot that cruises at full-rich is not only damaging his engine and fouling plugs, but is burning up to 55 percent more fuel than at the BE setting! Always lean at least to peak EGT when cruising with less than 65 percent power.

How much Power?

One of the basic functions of the aircraft designer is the sizing of the aircraft such that the selected powerplant is correct. An engine too-small for the aircraft results in inadequate climb in high-altitude summer conditions or an unacceptably long takeoff roll. Too large an engine is wasteful of fuel because either the high cruise speed is at an inefficient flight condition for the airframe (low cruise lift-to-drag ratio), or the engine itself is inefficient when throttled back to obtain the speed for a good lift-to-drag ratio.

If a designer attempts to select an engine for optimum cruise efficiency, i.e. at a flight condition for maximum miles-per-gallon he finds the engine inadequate for climb. This situation is not unlike that of the automobile designer who finds his vehicle is cruised at a speed far in excess of that for the best mpg. However, the designer knows that the airplane should not operate at best L/D (or best mpg) anyway, since this is not practical unless you are setting a distance record. Increases in speed above but near the best mpg speed result in only small losses of mpg. But, as the speed increases considerably above the best mpg condition, the mpg drops drastically. The big question, then, is how fast should you really fly? If this question can be answered, then the designer can size the engine for this practical speed.

Aerodyanmicist, Dr. B. H. Carson of the U.S. Naval Academy has published an excellent analysis of the fuel efficiency of light planes (AIAA publication 80-1847) and has presented theoretical rationale for practical cruise efficiency. His interesting technical treatise is beyond the scope of this article, but the summary of findings is of

interest to pilots. Rather than focusing on the cost per distance (mpg), he finds the speed that gives the minimum cost per speed. This "cruise optimum" speed corresponds to minimum outlay in extra fuel (over best mpg) per increment in additional speed. This speed corresponds to the closest approach of the airplane to a "technology barrier" of efficiency proposed by Gabrielli and Von Karman in an article "What price speed?" published in Mechanical Engineering Vol. 72 October 1950.

This "cruise optimum" speed, at 32 percent over the speed for best mpg, results in a 16 percent increase of total fuel used, requiring a 52 percent increase of power and saving 24 percent of flight time. This speed is regarded as the most productive use of excess fuel for cruising. The pilot should consider it his best "economy" cruise speed.

Accepting this theory, lets see what the resultant engine size is for the Long-EZ. At 8000 ft. altitude and 1325lb. weight the "cruise optimum" speed is 139 kt. (160 mph) and required 47 thrust horsepower (55 brake horsepower). This is a power setting of less than 48 percent power when using the 118 hp O-235 Lycoming. This suggests that, for 65 percent power cruise (to allow operation at lean side of peak EGT), the ideal engine for a Long-EZ should have 86 BHP. However, here is where the theory breaks down. The "Long" is a fast aircraft for a fixed-pitch prop application. Thus, with the low prop efficiency at slow speeds, it requires a 100 BHP engine for satisfactory take off performance.

The larger engines, 160 BHP for example, are wasteful of fuel at any speed. This is because specific fuel consumption (SFC) increases as the engine's power is reduced below 75 percent. The accompanying graph obtained last month shows this trend. Data are for best economy setting, about 50 degrees F on lean side of peak EGT.

If a Long-EZ is cruised at "cruise optimum" speed, its O-235-L2C engine will burn 8 percent less fuel than would an O-320-B at the same speed. (48 percent power for the O-235 and 36 percent for the O-320). If both engines were run at 65 percent power the O-320 would burn 22 percent more fuel than the O-235 for a given trip.

The following table shows data from a computer printout using the performance parameters for the Long-EZ, and assuming sfc equal 0.5.

Long-EZ weight equal 1325 lb.
Sea Level. * denotes 8000 ft.

Data for sfc equal 0.50

GRAPH "FUEL SPECIFIC AT BEST-ECONOMY MIXTURE" OMITTED

Weight Control.

CAUTION - Weight growth generally occurs late in the building project. The following scenario occurs during most homebuilt aircraft projects: Careful weight control is exhibited in the fabrication of the various bulkheads, wings etc., in building the basic structure. The builder is optimistic about the prospect of having a light weight aircraft, because all his components meet or beat the various weight goals. Then, when he begins the final stages of outfitting and finishing he relaxes his concern for weight control. He says "oh, this is only a few ounces, a small percentage of the total weight". Forgetting that the addition of many seemingly insignificant items results in a large total weight, he proceeds, expecting to attain a light empty weight. Another factor is present that he is not aware of. This is the existence of the Phantom Weight Law (PWL). The Universal PWL states that "additional weight of 3 to 10 percent of the empty weight will sneak into an aircraft (usually at midnight when the lights are out) between the time the weight engineer is confident he has accounted for everything and the time the aircraft is rolled onto the scales. This Phantom weight will remain in the aircraft and grow, but will never be accounted for nor rationalized"

The biggest trap is the non-concern for each gram of additional weight. Example: a two-inch BID tape installed at two and a half inches wide - seems insignificant? Yes, but that part is 25 percent overweight. Using the next size electrical wire - seems insignificant? Yes, but that part is 25 percent overweight. A small knob that is 25 percent heavier than another, a 5 lb rather than a 4 lb seat cushion, etc. Note that acceptance of these kind of items throughout the building and outfitting can result in an aircraft more than 100 lb overweight!!

Patch Contest

Our patch/emblem contest (see CP 27) has been extended until June 10th. We'd like to get more entries. Try to submit something that is not complex and not with a lot of words. An easily-recognizable symbolic shape or shapes and the letters RAF or RUTAN. We want it to represent not just one of the various airplanes, but a general theme of our aircraft designs. Do submit an entry even if you have already sent one in. The more the better. We will try to get jacket patches made before Oshkosh '81 convention.

FLASH - The fifth Long-EZ to fly!! Max Bradley of North Dakota. Congratulations Max.

Oshkosh - Accommodations.

Nat Puffer provides the following report:
A formidable problem presented to the first time VariEze/Long-EZ pilot flying into Oshkosh, is where to stay. Even with Long-EZ baggage space, it is difficult to pack enough camping gear for a week. If you are fortunate enough to find a place in town, there is still the commuting problem.

There is a solution. Oshkosh Recreational Vehicles has offered to park all of the camping fold out trailers he can muster in Paul's Woods one week ahead of time to get a good spot, for VariEze/Long-EZ pilots for a mere $125.00 ($10.00 deposit required in advance). You will also have to pay the advance camping fee, even though the trailer is not occupied. These trailers sleep 6, (get together with friends to share the tariff) have heaters, stove, sink and ice box. If you can't carry the rest of your gear in your VariEze, build a lighter one!!

Supply is limited, first come first serve.

International VariEze Hospitality Club
Fly in at Taos, New Mexico over the 4th of July weekend. Charles and Joan Richey (N13EZ) are the organizers and they report that they have 10 confirmed VariEze/Long-EZ and would like bunches more.

Chuck says it is not necessary to be an IVHC member, all interested parties may attend. Taos is in high country, a very beautiful area, should be a great weekend. Contact Chuck and Joan Richey for details.
600 S. Melendres,
Las Cruces, NM 88001 (505)523-1300

CAUTION
Never rotate the nose beyond the angle that places the canard on the horizon. **SKETCH OMITTED**

Carburetors for Long-EZs

Most 0-235 Lycoming engines come equipped with a Marvel Schebler carburetor without an accelerator pump. This carb is a MA3A and various configurations (10-xxxx numbers) are found. N26MS has a Marvel Schebler MA3A and the configuration number is 10-5199. This carb has no accelerator pump and we therefore have to use a primer to start the engine. A direct replacement for this carb with an accelerator pump would be a Marvel Schebler MA3PA - 10-5220. If you wish to order a brand new Lycoming engine from a Lycoming dealer we feel that probably the optimum engine for a Long-EZ is as follows:

Lycoming 0-235-L2C
Must have mechanical fuel pump.
Can not have spin-on oil filter,
instead must have standard oil
screen and housing.
Marvel Schebler MA3PA Carburetor
Part #10-5220.
No provision for primer required.
Must have Slick magnetos,
Bendix will not fit into the mount.

If you already have an 0-235 engine with the standard MA3A carb (no accelerator pump) you can use a primer, which works fine, or you can get an MA3PA. Various other 10-xxxx numbers can possibly be used. According to Avco Lycoming, the following numbers have all been used on 0-235 engines:

MA3PA	10-5257	Economy jets, slightly
	10-5220 E*	different at full rich
MA3PA	10-5267	
or	10-5220 EN*	Approx. 4% leaner
or	10-5257 N*	

* E, EN and N designate field modifications to these carburetors.

Accident

Letter from Alden Andrew, 24531 Vanessa Dr., Mission Viejo, CA

Dear Burt,

This note is to alert VariEze owners of problems that made me an ex-owner! I had the Brock fuel caps as specified in the plans. As per original instructions, a vent hole was drilled in the cap for the auxiliary fuselage tank. I did not modify the auxiliary cap with the aluminum tube as per CP 25 page 4.

Recently I removed the left main fuel cap and went to the restroom while the attendant put in the fuel. Upon my return, the left cap was on and the attendant was fueling the right main. I replaced the right cap and went flying. Shortly after take-off I was notified over the Unicom that fuel was being dumped overboard. Sure enough, the attendant had set the left cap on but had not engaged the Dzus fastener and I had neglected to check or notice that is was not secure. I landed immediately and discovered that the cap had hit the prop and left a gash 1/2" wide and 5/8" deep about 4" from the tip. After this experience I considered putting a tether chain on the fuel caps but

business matters soon consumed my full attention and the idea went by the wayside.

With a different prop, the plane was again serviceable. On February 6, over the telephone, I gave permission for a 3,000 hour pilot (with 10 hours in my VariEze) to use the plane the next day. Before his flight he attempted to obtain fuel but the fuel pit was temporarily out. Even so, they removed the left main cap as well as the auxiliary cap and attempted to obtain some fuel that might possibly be in the long hose of the fuel pit. After this unsuccessful attempt the caps were replaced (with the un-vented cap being put on the auxiliary tank) and it was decided that with about 1 3/4 gallons in the auxiliary tank that the pilot and his passenger could make Corona Airport from the present Chino location (about 5 minutes). They took off on the auxiliary tank and at about 100' at 105 knots they lost power. In the knowledge that there was fuel in the auxiliary tank the pilot did not try to select the mains which still had adequate fuel. An off airport landing (?) was made in a rough grassy field. The nose wheel was left retracted. (The aircraft was forced to the ground at high speed and high rate of sink because of a fence ahead.) The plane came to rest about 300 ft from the original touchdown point. The pilot escaped with scratches and bruised legs and toes but no broken bones. The passenger was not scratched or bruised at all. The plane did not fare so well; collapsed main gear, main center-section spar broken and ripped off with the left wing, canard ripped off, the total front end from the trailing edge of the canard was completely severed from the rest of the fuselage, as well as the top and bottom kevlar cowling was ruined. The prop was horizontal at the time of impact so the prop, spinner, hub extension and engine were undamaged as was most of the instruments. The canopy was unscratched.

To sum it up, I would recommend either a mandatory change to include a ram air vent leading to the auxiliary tank or the tethering of the fuel caps.

As my 86 delightful hours in the VariEze has spoiled me, I desire another canard pusher. I guess a Long-EZ is the next project. Does anyone want to but a good VariEze canopy and a 96 hour SMOH Continental O-200 complete with hub extension, prop and spinner?
Sincerely,
Alden Andrew.

RAF comment: The two VariEze plans changes in this newsletter are intended to prevent recurrence of Aldens accident. We have before considered tethering the fuel caps, but were concerned that major tank damage would be done by a cap flailing against the surface. Note that, as was explained in CP 13 page 5, loss of a wing cap on a VariEze will cause all fuel to be slowly drawn into one tank (and overboard if tanks are more than half full) and result in fuel starvation, requiring the selection of the fuselage tank to maintain engine operation. Loss of a cap on a Long-EZ does not effect engine operation due to its left/right isolation and pumped fuel system. Also, the Long-EZ's caps are outboard of the prop to eliminate prop damage should a cap not be secured.

BUILDER HINTS

Exhaust gaskets. It is an excellent idea to use blow-proof exhaust gaskets on your VariEze or Long-EZ or VariViggen. If you plan on installing cabin heat, blow proof exhaust gaskets should be considered mandatory. These are available from Aircraft Spruce or Wicks Aircraft, and for your small Continental engine order part nbr 627429, for all Lycoming engines order part nbr 77611.

Long-EZ. Method to lap outside skin plies at bottom CL fuselage to avoid a bump.

DRAWING OMITTED

Aileron Hinge Pins.

Long-EZ and VariEze aileron hinge pins. The piano-hinge pins have in some cases been wearing out much more rapidly than they should. This is characterized by evidence of aluminum stain aft of the hinge on the aileron surface and excessive hinge free-play. The wear is caused by vibration of the hinge and can be eliminated if the pin is snubbed to prevent rattle. For new construction, before final installation of the hinge pins, bend them into a gentle "S" shape. This will ensure that they don't rattle in the hinge. A rattling loose hinge pin will cause excess wear to both pins and hinges.

DRAWING OMITTED

Back Seat Thigh Support.

This little item really makes a difference to back seat comfort. This position works excellently for people from 5'4" to 6'4". Fabricate from R45 foam with 1 ply BID on each side. 1 pc. 4" x 19", 1 pc. 7" 19".

SKETCH OMITTED

Hints from builder.
1) It will save time in building and finishing if you are neat in everything you do. For example, protect foam and finished parts from slopping or dripping epoxy on them. Example, when laying up spar caps, do like a surgeon and cover and tape off adjacent foam areas to protect them from epoxy. **SKETCH OMITTED**

In a similar fashion, protect finished parts by covering and taping them against drips, runs etc.

2) When gluing foam cores together, use minimum micro to prevent large excess from oozing out. Tape edges of cores first, so you can clean off excess without smearing it across the foam. **SKETCHES OMITTED**

3) Before sanding cores, undercut seams to avoid high spots, or breaking loose micro or 5 minute epoxy which will damage foam. Its easy to fill undercut areas again before skinning.

Long-EZ - Prop Position

The forward face of the prop hub should be at F.S. 158.8" and at W.L. 21.83. This includes the recommended 3" prop extension.

Long-EZ Main Gear

When drilling the 5/8" diameter holes through the main gear attach tabs, the 5/8" counter-bore tool drills a slightly undersized hole in the fiberglass laminate. An easy way to get this hole to fit the LMGA tube is to use a dremel sanding drum. Do not use it in a dremel tool, rather chuck it up in your 1/4" power drill (much slower rpm) and it will make the hole a perfect fit on the tube.

Clarification, Page 5-2 Long-EZ

A couple of builders have been confused at where to install the 3-ply UND stiffeners on the top insides of the fuselage sides. (page 5-2 step 2). The adjacent sketch will clarify this.

SKETCH OMITTED

Cowling storage

When you get your cowling you may not be ready to use it right away, in fact some builders store cowling for months, occasionally years! A cowling left laying around can change shape considerably. For easy fitting when you need it, clamp both cowl halves as shown to a length of 2" x 4" lumber. This holds the cowl in the correct shape to prevent long-term warping. **SKETCH OMITTED**

Wherever you have a glass-to-glass laminate (trailing edge of wings, winglets, canard etc.) do not leave the overlapped skins unsymmetrical. Always clean up the edges (see sketch) to a smooth surface without a joggle. It is poor practice to leave areas joggled even during construction, since a blow on the untrimmed edge can result in delamination. **SKETCH OMITTED**

PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the aircraft does not need to conform to certification requirements. This allows experimentation by the homebuilder, giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

CATEGORY	DEFINITION
MAN-GRD	MANDATORY, GROUND THE AIRCRAFT. DO NOT FLY UNTIL THE CHANGE HAS BEEN ACCOMPLISHED.
MAN-XXHR	MANDATORY, ACCOMPLISH THE CHANGE AT NEXT CONVENIENT MAINTENANCE INTERVAL OR WITHIN XX FLIGHT HOURS, WHICHEVER COMES FIRST.
DES	DESIRED - STRONGLY RECOMMENDED BUT NOT REQUIRING GROUNDING OF THE AIRCRAFT.
OPT	OPTIONAL - DOES NOT EFFECT FLIGHT SAFETY.
OBS	OBSOLETED BY A LATER CHANGE
MEO	MINOR ERROR OR OMISSION.

Jim makes very nice tie tacs, charms, pendants of your N number, for example N79RA. This is made out of gold or silver to your specification. Largest possible size is 4". Jim charges $50.00 for his labor plus the price of the precious metal used.

Advanced Composite Lightweight Cowlings

We announced the availability of these cowlings in CP #27 page 5. Unfortunately the supply of graphite woven cloth has since become much more difficult to obtain and almost twice the price. This means that we have had to turn to Kevlar cloth. Any builder ordering a graphite cowl, should be aware that unless he gets an early one, he probably will receive a Kevlar cowl. It is within 1 lb. of the weight of the carbon cowls. The Kevlar cloth is covered, both inside and out with fiberglass, to avoid the sanding/fraying problems experienced with Kevlar. We have approved the use of Kevlar in the cowlings, in fact we have one on display here in Mojave for inspection.

Aircraft Spruce or Wicks Aircraft supplied Wheel Pants

These wheel pants for VariEze/Long-EZ 3.40 x 5 tires should be available by the time you read this. Those for 500 x 5 tires will be available in a month.

The correct method of installing these wheel pants is as follows: Install 11 K100-3 nut plates in the flanges, evenly spaced. Drill and countersink #10 holes for AN509-10R8 screws. Jig the pant halves loosely in place and carefully mark the top for the gear leg cutout. Cut this out and reposition the pant, making sure it clears the brake caliper and that the incidence is correct. It is best to have the pant about 3 to 4 degrees nose down. Be certain to leave a 1/10" clearance around the brake line to avoid a brake leak due to the pant chaffing on the line.

Now, fabricate an aluminum bracket from .032" 2024T3 approximately 2.5" x 8", see sketch. This bracket mounts on the four axle mounting bolts in a horizontal position. Install two nut plates (K1000-3) in each bracket, and bend the bracket as shown to extend inboard one inch. Drill two #10 holes in the pant to match the bracket. Drill and tap the axle 1/4 x 28 (use a #3 drill). Now cut out 3 pieces of your 1/4" plywood (firewall bulkhead) and glue them together to make one piece 3/4" thick x 2" x 2". This piece should be pyramid shaped and should have an AN970-4 washer on top of the pyramid. Layup 2 plies of BID over this washer and plywood block lapping at least 1/2" all around

onto the inside of the wheel pants. After this cures, drill a 1/4" hole through the center of the washer, and you should be able to mount the pant nice and firmly to the gear leg/axle. Use low profile AN525 screws for low drag. **SKETCH OMITTED**

Pre-Fab Fuel/Baggage Strakes for Long-EZ

Fuel/baggage strakes will be available by June. These will consist of 4 large pieces (2 tops and 2 bottoms) vacuum bagged into excellent molds. The pieces join at a leading edge joggle joint, eliminating the TLE/BLE pieces, and they extend to match the wing. Installation drawings for these tanks will be provided.

These components will be sold direct by the manufacturer.

Questions and Answers

Q. Can I make a soft leather "boot" to cover the control sticks, in place of the fiberglass cosmetic covers shown?
A. Yes, we have seen several examples of this, and they looked excellent. The leather can be attached with contact cement or velcro. There must be no restriction to control stick travel.

Q. How noisy is it in a Long-EZ?
A. We ran a comparison with a Cessna 150 and a Long-EZ.

	Long-EZ	C-150
Taxi	82 dba	78 dba
Takeoff and climb	96 dba	92 dba
High Cruise	98 dba	91 dba
Low Cruise	94 dba	88 dba

Q. Can I use a voice actuated intercom?
A. Yes, we heartily recommend doing this, and also using good noise attenuating headsets. This makes conversation between pilot and passenger varieze, and also enhances your ability to hear and understand ground controllers. Cockpit speakers should not be used in VariEze's and Long-EZ's. With good headsets (we use David Clark H10 type), the pilot-perceived noise level is considerably quieter than in a Cessna without headsets.

Q. Can I move my B.L. 45 rib outboard in my Long-EZ fuel tank in order to carry more fuel?
A. Absolutely not. This will give you an aft c.g. condition, even with a small quantity of fuel on board. Long-EZ's should have enough fuel/range to satisfy anyone.

Q. Why is my L.B. 12345 weldment from Brock, for my landing brake 1" too short?
A. It is not too short. You missed the instruction on page 9-1 and CP #26 page 6, LPC #35, to go to page 24-1, step 2, where you will find this called out. The reason is that this weldment was made for

VariEzes originally, and they are 2" narrower at this point. Rather than make a new part, we accepted mounting the L.B. 18 brackets 1" left of center on the landing brake. We have tested it in this configuration and it works excellently.

Q. Can I substitute a Stewart Warner #8406J oil cooler for the recommended Harrison #8526250?
A. Yes.

Q. I want to install the NACA inlet. Can I do it before glassing the bottom of the fuselage?
A. No. The normal glass on the bottom of the fuselage is required structure. The NACA inlet per Tim Gehres and Steve Wood's plans is purely an inlet-shape add on, and provides no structural tie between the bottom longerons.

VariViggen News by Mike Melvill.

Arthur Schwartz has accumulated some 42 hours and has had the initial restrictions lifted. He flew down the coast under the NY. TCA to Dover, Delaware, where he met George Semac. George's VariViggen is at the airport, and has been signed off for flight, so we will soon have another Viggen in the air. We have heard, second hand, of yet another Viggen at Redding, Pa. Apparently this airplane is doing taxi tests. Unfortunately I do not have this builder's name.

George Craig sent in a few excellent photos of some of the detail work he is doing on his VariViggen. (see page __) George has built the worm/wormgear main gear retract system, as used in my N27MS, and his workmanship looks great. George has spent a lot of time and effort designing neat little features to make future maintenance easier. A work of caution here: It is really easy to fall into a trap. You figure, heck, this little modification will only weigh a 1/4 lb. more, but the problem is it will sneak up on you. When you finally weigh the airplane, it can really be a shock. When I weighed N27MS I was stunned to find it weighed 1252 lbs. Burt's N27VV, the original prototype only weighed 1070 lbs. This made mine almost 200 lbs. heavier. This means I fly even solo, as though I had a 182 lbs passenger on board, and it really shows up on a hot day at high altitude. Actually I would give an awful lot to have my Viggen weigh 100 or 150 lbs less. Remember, the weight buildup takes place in the finishing area, after basic structure is done. Usually a builder gets the airframe structure done with little difference in the weight, and then he puts instruments in the back, map reading lights front and back, sound proofing, upholstery, wall to wall carpeting, etc., and before you know it, you have ruined the utility of your aircraft.

George is building his Viggen as a "stand-off" F14 Tomcat replica. He had built fiberglass seat frames to simulate ejection seats. A military paint job would really look impressive. I cone suggested something along this line for my Viggen, but I was immediately and strongly overridden by my wife Sally!!

Frank Tomko has requested clarification on a couple of items and I thought maybe answering them here instead of in a letter would help other builders. He asked where the hole should be cut through the firewall (F152) for the wiring bundle and for the throttle, carb heat and mixture cables. The best place I found for the wiring bundle is at B.L. 7.5 and W.L. 15.5. A 1" diameter hole accommodates all wiring necessary. The wiring bundle could be supported with a rubber grommet or RTV silicone. Either way, precautions must be taken to ensure that the wiring is not chaffed by the stainless steel firewall. The throttle, carb. heat, and mixture control cables can go through the firewall at B.L. 7.5 and W.L. 14. Again a 1" diameter hole with a rubber grommet works fine.

Ken Winger of Tulsa, Ok. reports that he will be at Oshkosh this year. Ken has his Viggen through silver at this time, so he is getting close. Ken's Viggen has a Lycoming O-360 (180 hp) and SP wings, and he has really tried for light weight structure. Should be a performing airplane.

N27MS continues to run well, and we do fly it virtually every Saturday here at RAF for demonstration purposes. Of course it will go to Watsonville and Oshkosh at least and possibly other flyins. Maintenance has been minimal, the hour meter quit metering and had to be replaced. Apart from oil changes and putting gas in it, she has been running like a top.

Jim Cavis has written to say that he is giving up on his Viggen. Jim has lost his medical due to an eye problem, and has elected to sell his project as is. We do not normally advertise airplanes in the CP, but we are very familiar with Jim's Viggen. Jim reports that it is about 90% completed and that he has most parts necessary to complete it. Jim's project is a standard wing (foam/fiberglass) 180 hp Viggen. Contact Jim for further information -

LONG-EZ

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE
The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and

headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE

At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY

The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to 27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES

Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the

manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

Brief Long-EZ specifications/Performance
Engine Lycoming 0-235 108 hp.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200

SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 29. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 29. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 29. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 29. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 through 29.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

RAF is very pleased to announce the addition of Larry Lombard. Larry joined us in May 1981. Larry built and currently flies his own VariEze N15LL (see photo) and has been involved in the building of several VariEzes in the Sacramento area. Larry will be heavily involved with the self launching sailplane development and building, as announced in CP 28. **PHOTO OMITTED**

RAF Activity lately has involved aerodynamic development of our self-launch sailplane design, research on composite component assembly methods and structural arrangements, design support for a new twin-jet research aircraft being built for a major aerospace company, builder support and the Cafe 250 participation.

Canard Pushers from 1 to 82

CAFE 250 - The first Competition in Aircraft Fuel Efficiency race was held last month in Santa Rosa, CA. It was well attended, with 27 commercial and 20 experimental aircraft. This is the most extensive fuel efficiency competition ever run for general aviation aircraft. It is not an all-out miles-per-gallon race, but one whose best result is obtained at about 65% power. The fuel efficiency factor is calculated as follows:

FEF = speed x mpg x square root of payload

Where speed is in mph, mpg is statute miles per US gallon and payload can be up to 200 lbs. per seat, but not to go over gross weight.

While a VariEze can attain an FEF or 140,000 + in level flight at altitude, it's scores were under 100,000 on the race course when faced with winds, required climbs and descents, time in the pattern and fuel to taxi.

The competition is very interesting technically and a lot of fun to fly. The official placings are listed below. It should be noted that the placings for the small efficient aircraft may be in error due to the inability to accurately determine the small amount of fuel used by weighing the entire aircraft.

For example, aircraft weighing inaccuracies on only 2.4 lbs. per weighing (0.8 lbs. per scale) would have swapped the first place and third place aircraft's positions. Variations within the weighing scale resolution (0.5 lbs.) would drastically change the FEF of a Quickie. The Long-EZ that placed 17th appeared to place 5th if fuel used was based on sight gage and totalizer readings. Race officials are planning to minimize these variations next year with methods to more accurately measure fuel burned.

PLACE	AIRCRAFT	PLACE	AIRCRAFT
1	Q2	25	CESSNA T210
2	QUICKIE	26	CHEROKEE 180
3	VARIEZE	27	GRUM TIGER
4	QUICKIE	28	FORMULA I RACER
5	VARIEZE	29	ROCKWELL 112
6	GLASAIR	30	TWIN COMANCHE
7	VARIEZE	31	CESSNA 182
8	VARIEZE	32	CESSNA 172
9	VARIEZE	33	PIPER PACER
10	MODIF BONANZA	34	AZTEC
11	MODIF MUSTANG	35	CHEROKEE
12	QUICKIE	36	CESSNA 175
13	LONG-EZ	37	CESSNA T206
14	MOONEY (DISQUAL)	38	CESSNA 172
15	MOONEY 201	39	WING DERRINGER
16	POWELL SPECIAL	40	CESSNA AIRMASTER
17	LONG-EZ	41	CESSNA 175
18	RV-4	42	CESSNA 172
19	MOONEY 201	43	PIPER PA-11
20	LINNMING MUSTANG	44	CESSNA 310
21	DEFIANT	45	BELLANCA 14-13
22	COMANCHE	46	CHEROKEE
23	BUSHBY MUSTANG II	47	BELLANCA 14-13
24	KR-1 (DISQUAL)		

Note that the top 9 winners were fiberglass aircraft, and the top 5 did not have a horizontal tail! The Q2 won the experimental trophy. The modified Bonanza that won the commercial trophy had won the Paris - New York - Paris race two weeks before. The Defiant won the best twin trophy, beating also all the commercial singles except the Bonanza and Mooney 201.

Pilots in the race flying RAF aircraft were:

Jeana Yeager	N26M	(Mike & Sally's Long)
Mike Melvill	N4EZ	(Prototype VariEze)
Larry Lombard	N15LL	(The winning VariEze 3rd overall)
Dick Rutan	N79RA	(Prototype Long-EZ)
Burt Rutan	N78RA	(Defiant - Pat Storch navigator)

Sally Melvill had planned to fly N26MS but was unable to attend.

WORLD DISTANCE RECORD - Dick Rutan

Another World Class distance record now belongs to the Long-EZ. 4563.35 miles straight line distance in C1B (1000kg) is the new record subject to ratification by the FAI. That is the great circle distance between Anchorage, Alaska and Grand Turk Island in the British West Indies near Puerto Rico. The flight time was 30.08. The total fuel burn was 142 gallons, that works out to 151.4 average ground speed and 4.71 gph. We used only 1.8 qts. of oil.

We found the logistics of getting the aircraft (N169SH) to Alaska and recovering it back home was quite an undertaking. We departed for Alaska on May 22 and got

---

back to Mojave on June 13. Most of the time was spent waiting for favorable winds at Anchorage. For a while it looked like we should have started in Puerto Rico and flown to Alaska. But after waiting 14 days the Weather God pushed a high pressure ridge out of the Gulf of Alaska that gave us some tail wind over Southern Canada and the Northern mid U.S.A. But the rest of the route was a no-help cross wind to a light head wind in Alaska and over the Atlantic. The over all wind factor was only +6 knots.

I flew at between 12 - 13 thousand feet and averaged 153 mph true airspeed. The reason that does not compute is because the actual airway distance was 4690 sm and the route time was 29.5 hours. When I got to Grand Turk I was feeling good and had plenty of fuel so just flew around long enough to log over 30 hours! I landed with 6 gallons fuel, enough for another 200 miles but the next over-water leg was 363 miles so Grand Turk was where it had to be.

Luckily for me I had none of the fatigue problems I had on the 33.6 hour closed-course record flight. I was in better physical shape and was well rested before take-off. Also one big factor was all the adrenaline pumped into my system during the night-long weather system I flew through on only a turn and bank gyro after my vacuum pump failed. It did get a little uncomfortable during the last part of the flight because I had on a lot of arctic clothing. It was quite a difference

from my 4 a.m. Alaska take-off to the mid-afternoon Caribbean tropical hot-humid weather! Latitude change for the flight was 40 degrees, longitude changed 79 degrees.

We are a little disappointed that we did not make 5000 miles. We were short because we just could not find any more room for fuel inside the aircraft, the lack of good tail winds and the time spent at low altitude punching through the weather. Also, the bigger 0-320 engine used more fuel than Burt's 0-235 Long-EZ. The weight limit in the class was 2204 lbs and my gross weight at take-off was only 2033 lbs. I could have handled the 2200 lbs. easily. The take off roll was only 2800 ft. and at a stabilized climb speed of 140 mph indicated I had an initial climb of 600 fpm.

When I did the closed-course record in the prototype Long, I had used a cable between the main gear axles to prevent excessive gear spread because the prototype had an early, more flexible gear. My Long has the standard main gear like all the homebuilt Longs, and it did not need any additional support. The wheel camber was only slightly outward at my take off weight of 2033 lbs.

All in all we are happy with what we got. Next is the world altitude record and some of the long-distance speed records. Most are within EZ reach of the Long. I would like to see more homebuilders involved in breaking some of the records. It is not that complicated and the challenge is a lot of fun.

LBF RACE - Oshkosh 81
RAF plans to offer prizes to the first two VariEze/Long-EZ finishers in the Baker competition. (fuel corrected speed).

HOSPITALITY CLUB FLYIN
Taos, New Mexico. Chuck and Joan Richey have organized this flyin and at press time they have 22 VariEze and Long-EZs and 39 people signed up! Looks like this should be another super flyin. Rafting trips on the Rio Grande are also available. Builders and flyers are coming from as far away as Minnesota, CA, Utah and Texas.

COLOR OF COMPOSITE AIRCRAFT
In spite of a number of composite airplanes showing up around the country with various color schemes, RAF does not approve any color but white. Trim colors must be limited to the vertical surfaces. Do not paint a dark stripe on the top of the wing. Since the introduction of the European glass sailplanes in 1961/62, there have been no cases of the composite sailplanes having any damage from heat, and all of them are white. They cannot be certificated if painted any other color.

There can be no doubt that a dark color will reduce the useful life of your airplane in the long-term, and could lead to even more serious consequences should the structure get too hot. White guarantees that your airplane will never go above about 10 degrees ambient air temperature.

The colors, even the lighter and metallic ones can get hot enough in desert ambient conditions to seriously weaken the epoxy matrix and degrade the foam core. Measurements taken at Mojave of several

airplanes and trim stripes have shown the following results using a surface pyrometer.

Ambient	105 F
White (different shades)	110 F to 116 F
Light Yellow	128 F
Grey	135 F
Light Blue	130 F
Dark Blue	168 F
Dark Red	165 F
Dark Green	175 F

FULL-CORE COMPOSITE SANDWICH WINGS
RAF pioneered the structural method of using the hot-wire styro block to form full-depth foam core wings in 1974. We have built over 60 flight-hardware flying surfaces using this method in the development of the S.P. VariViggen, VariEze, Quickie, Defiant, Long-EZ, AD-1 and other aircraft.

The method has since been used on other types, including an STC'ed vertical fin for the older Mooneys. It is estimated that approximately 500 full-core aircraft are now flying, logging over 100,000 flying hours.

The major advantages of full-core are the ease of moldless construction, the accurate contour maintenance under airloads, and elimination of moisture traps. Critics have claimed that full-core is heavier than the hollow wing with standard skins. Our analysis has shown the weights to be very close. However, we have built and tested wings designed to the same criterias (hollow vs. full core) and have found the hollow wings to be heavier. In addition, the hollow structural configuration is more susceptible to workmanship errors that can result in structural failure. This is due to the presence of peel loads and blind rib closeouts. In addition, the hollow structure flexes, has more points of concentrated stress and is more prone to catastrophic failure should a joint open up (leading or trailing edge).

A builder who had built a VariEze, Quickie, Long-EZ and Adventure is now building a homebuilt with molded wing skins. He reports that despite the large molded parts, the man hours in the wing are at least 50% more than for both full-core Long-EZ wings. This is due to the many ribs, jigs, control system parts etc.

RETRACTION!
Regretfully we received incorrect information on Max Bradley's Long-EZ as reported in CP 28 Page 6. This aircraft has not flown and is currently only about 80% complete.

The fifth Long-EZ to fly belongs to Richard Sparkman of Maples, Florida. Richard has 8 hours on it at press time and is currently working out an over rich carburetor. Richard is planning on being at Oshkosh. His airplane is full IFR equipped. Congratulations Richard!!

RAF Patch Competition!
At long last we have a winner. Congratulations to Chet Rhamstine of Mt. Clemens, Michigan. We are not printing a copy of the patch that

Chet designed as we feel that once it is sewn it will look a lot better than just a copy. We hope to have the patches available for Oshkosh.

Warning - Loss of Prop!
Dick recently had an experience with his Long-EZ that would raise the hair of the most experienced pilot. He lost the entire prop and spinner while cruising at 10,000 ft. over a solid cloud deck. After watching the prop cascade away he received radar vectors from center to allow a successful approach to an airport, under weather conditions of 1/4 mile visibility in fog. Investigation revealed that the all-important bolt tension (required to transmit torque through faceplate friction) had been lost when the prop dried out in desert conditions after exposure to the humid-wet Caribbean climate at his world-record arrival location. Note the added caution in the plans-change section of the newsletter. Also, do not, do not exceed the recommended interval on prop bolt torque check. (Owners Manual, Appendix III).

ACCIDENTS
Power Loss - A south eastern VariEze crashed into trees after power loss on its first flight. The power plant was a conversion of a Chevy Corvair automobile engine. The aircraft was destroyed. The pilot was not injured.

Known Icing conditions/fuel management - A Midwest VariEze pilot began an extensive trip in IFR and icing conditions. His flight was a classic condition of many things going wrong in combination. He reluctantly accepted an altitude assignment in known icing conditions, only 1,000 ft. above the MEA. The pilot became quite busy as ice was building, switching the single Nav to identify intersections then noting an impending failure of the gyro horizon - nose high at normal airspeed. Also, he reported a Nav problem and center lost radar track of him. They were talking to him but did not know his position. At 40 minutes from takeoff the engine abruptly quit cold. He descended through the clouds breaking out at about 500 ft. AGL and put it in a freshly plowed field approximately 30 miles off course, carrying a large amount of airframe ice. The pilot received a fractured vertebra. The aircraft's wing, belly, landing gear and canopy received major damage. Investigators found the fuselage tank empty, speculating that the pilot had departed on the fuselage tank and the engine failed due to fuel exhaustion. Probably the pitot-tube had iced up resulting in his thinking the speed was ok and the gyro horizon was failing. His airspeed was thus too low to allow a restart even when main fuel was selected during the power-off descent through the clouds (windmilling not maintained).

Many builders, including this one, have modified the positioning of the fuel valve on the VariEze, defeating its feature of reminding the pilot (by interference with his right wrist) that the fuselage tank was selected. There have now been two accidents caused by a combination of incorrect fuel management and defeating the interference design feature of the valve handle.

ACCIDENT ANALYSIS

As you know from reading the Canard Pusher, we report a synopsis of each accident and make recommendations to builders/operators on any item we feel should be changed or emphasized to decrease the probability of reoccurrence. We have reviewed the data available and have found one factor that is significant. A high percentage of the accidents (minor and serious) have occurred within the first few flights after a new owner has bought the airplane from a previous owner. Statistically, you are far more likely to have an accident flying a homebuilt built by someone else. This is true for experimentals, not just for VariEzes. For example, an all-metal type that recently was grounded for a series of structural failures - all the failures occurred after non-builders had bought the airplanes.

The factor may be a combination of inadequate familiarity with the airframe and systems, inadequate checkout and inadequate transmittal of documentation. Putting things in perspective, it is important to note that the builder is an aircraft manufacturer. As such, he may be responsible to a buyer for the quality of the machine and for properly educating the buyer in it's safe use and the extent of his flight test program. We at RAF provide builder support to our customers - those who may need assistance or have questions on how to interpret the plans to build or how to interpret the Owners Manual to fly the completed aircraft. But, if you sell your airplane to another person you cannot expect that we can support him. He must go to you, the aircraft manufacturer. For example, if he needs to do a fiberglass repair, but does not have the plans and educational material he will not know how to do the job. He needs to get that information and documentation from the manufacturer.

Homebuilt accident record statistics were reported for a three year period by The Aviation Consumer last year. They show an overall accident rate for VariEze of 2.59 (1.55 fatal) per 100 aircraft during the 3 years. Average for all homebuilt aircraft was 3.93 (1.07 fatal). We are not happy with this result, as we had expected the VariEze to be significantly better than the average homebuilt due to it's strong structure and good stall characteristics. Structurally the fiberglass VariEze has a perfect record - no inflight airframe failures in 100,000 flight hours. Also, there have been no fires either in operation or due to accident impact.

Data published by one source show that flying amateur-built aircraft is statistically a very risky sport, with an accident rate (per individual) higher than that for racing cars.

LONG-EZ FUEL SYSTEM

Do not change the fuel system. This system was carefully and thoroughly flight tested at all attitudes, and works very well as per plans. Several builders have asked if they could convert the fuel system to a "both on" situation. Absolutely not! Both fuel tanks feeding the carb together will only work on a gravity system. The Long-EZ does not have enough fuel "head" to use a gravity system. Therefore we use a pumped system. That is, the primary pump is a mechanical, engine driven pump, backed up by an electrical boost pump. This is similar to most low wing airplanes, Grumman Tigers, Cherokees etc.

If you try to pump fuel out of two tanks at the same time, it can draw from one tank only, until it is dry then you will get air, and in spite of having one tank almost full of gas, you will flame out and have to land because of fuel starvation.

Be very careful of fuel systems, they must be absolutely fool proof in order to work reliably and consistently.

NACA FLUSH INLET
We are getting a lot of inquiries about this and frankly we really cannot make your decision as to whether or not you should install it on your VariEze or Long-EZ. Here are the facts. This is all we can tell you. Please do not ask us to help make your decision.

1) You have to build the bottom of your fuselage per plans whether you use the NACA inlet or not, since this is required structure to tie the two bottom longerons together. The NACA inlet is an aerodynamic cosmetic add-on, and provides no structural tie between the fuselage sides. The NACA inlet is homebuilder-carved (no prefab parts are available) and spliced in to the standard cowl. You will not need the "CI" cowl inlet part.

2) The NACA inlet works well for cooling and is lower drag than the ram scoop, adding about 3 knots more airspeed. Since the fuselage sides are lower in the area of the main gear you get a better aerodynamic juncture between the main gear and the fuselage.

3) The sex change operation (going from the "male" ram scoop to the "female" NACA inlet) will add about 4 to 6 lb weight.

4) You may elect to install the flush inlet for aesthetic reasons only. We like the side profile view of the female EZ very much, and almost everyone who has seen it agrees.

5) RAF did not develop this installation, and therefore we cannot support you in building it. Tim Gehres and Steve Wood did all the work on it, they sell the plans, and they will support you if you have any builder questions. Contact Tim or Steve at:

Wood and Gehres Inc.
105 Appleblossom Ct.,
Orlando, FL 32807

Plans cost $20 and are very easy to follow.

SAFE-T-POXY WORKING TEMPERATURE.
Builder feed-back has indicated some difficulty using the Safe-T-Poxy in cold climates. Typical situations are where most EZs are built in garages that are difficult to heat in the winter. Problems are where the builder will heat up the room/garage (air only) and go directly to work but the epoxy, glass, parts, tools etc are still cold-soaked. In use, cold epoxy wets slowly and greatly extends the time to wet the cloth properly.

The Safe-T-Poxy has a higher viscosity than the previous resins, thus requiring a higher working temperature to use, especially on the larger layups. The high viscosity was selected for the Safe-T-Poxy to

eliminate the tendency of the previous material to bleed-out (inducing air in the layup during cure).

If you are building in a cold garage in the winter you can still use the new Safe-T-Poxy if you take the

---

following precautions:

1) Warm the resin and hardner evenly to 85-90 degrees F prior to mixing. Don't try to hurry this. We use a light bulb under the ratio pump 3-4 hours prior to use, or keep you resin jugs in a cabinet with a light bulb inside.

2) It's important to have everything thoroughly warm prior to starting to work. This also cannot be rushed. It takes time to get the parts (wings, foam blocks, etc) up to a stable temperature throughout. If you are starting from a very cold garage the warming process could take 4 hours or more. Don't think just because the air is warm that all the material is warm.

3) Use an electric hair dryer to warm the area as you work, being careful not to over-heat the part or epoxy. When, due to cool temperatures, a part is slow to wet out, a few quick passes with a hair dryer will greatly speed the layup time. Do not use a hair dryer to heat a cup of epoxy. This can give local hot spots and ruin pot life.

What shop temperature is satisfactory? That has a lot to do with the size of the job. Small jobs can be worked to as low as 65 degrees F but the working time will be excessive. It will also be more difficult to remove excess epoxy, resulting in a heavier part. On large lay-ups like the fuselage, wings, etc., where there is a lot of epoxy to drag around, 77 degrees F should be considered the minimum. That's epoxy prewarmed to 85-90 F and all parts, glass, foam, tools, table - everything up to 77 F for 4 hours then go to work. Those temperatures are minimums - add 5 to 10 F and your working time will be greatly reduced and parts built lighter. Optimum working temperature range for the Safe-T-Poxy is 77 - 95 F.

PLEXIGLASS HINTS FOR PERFECT CANOPIES.
1. Cutting: An abrasive disc powered by a high speed drill, a Dremel tool, or a hand held circular saw is recommended. We have found that abrasive cut-off wheels of aluminum oxide or silicone carbide provide excellent cutting results. A six inch disk is available at most hardware stores for around $3.50 A small grinding disc or Dremel saw disc will also give good results. Reciprocating saws like saber saws are not recommended and will probably break your canopy. A tool that progresses slow and hot on the canopy to grind through the canopy is best. Tape a poly plastic cover on the canopy and mark your outline with masking tape. Never cut a cold canopy. Allow the canopy to warm to 70 or more for at least an hour. Don't allow the canopy to vibrate or chatter during the cutting or it may chip and crack. Support your canopy on a flat surface so it will not twist or spread during the trimming. Duct tape is handy to hold things in place. Remember: cut slowly, don't push the cutter. Let the tool do the work. Be sure to

use eye protection. Plexiglass chips can be a problem in your eyes since they are clear and difficult to see.

2. Drilling: The drill should be ground off to a zero rake angle to prevent digging in, chipping and cracking the Plexiglass. A standard drill bit, ground with no cutting edge pitch, is a safe method of making holes. Be sure to make the holes oversize to allow for motion caused by thermal expansion and contraction. The drill bit should not be allowed to chatter or will chip and break the Plexiglass. Don't push the drill. Let it cut at its own rate.

3. Cleaning: A damp soft cloth or an air blast will clean the saw dust away. The damp cloth will also dissipate static electricity. To clean dirty plexiglass use plenty of water and a non abrasive soap or detergent. Dry with a clean chamois or soft cotton. Never use acetone, benzene, carbon tetrachloride, lighter fluid, lacquer thinners, leaded gasoline, window sprays or scouring compounds. Grease or oil may be removed with kerosene, white gasoline, naphtha or isopropyl alcohol. Small scratches can be buffed out with "Mirror Glaze" HGH-17 and a lot of rubbing. Hard automobile paste wax should be applied as a protective coating and buffed with a soft cotton flannel cloth. Do not use cheesecloth, muslin or shop cloths, they scratch. For deep scratch removal, procure a hand polishing kit from a Plexiglass dealer or your canopy supplier.

NEW EZ FIRST FLIGHTS.
We have not reported VariEze first flight names since CP 23. The following list is those who, based on our information, have made an EZ first flight since 12-79. If you know of someone who should be on this list please send us the name, address, N-number and date of first flight.

Vic Mondary	N500EZ	IN
Richard Clark	N89EZ	CA
Alex Dimuro	N22803	HI

PREFAB FUSELAGE SHELLS FOR LONG-EZ

When the second VariEze prototype (N4EZ) was built, we considered prefab fuselage skins. These would be 2-piece shells fabricated by vacuum-bagging a glass-foam-glass sandwich into a female mold. An analysis of cost and construction savings showed that the time saved was minor, particularly considering the extra work involved fitting the bulkheads and systems to the rounded interior.

Fuselage shells bagged into molds should have a potential of a weight savings and a savings in exterior finishing work. However, based on our components and the results of the prototypes which have been built both moldless and molded, the weights of completed ones. The molded-shell method is a good one for the bulky fuselages of side-by-side airplanes, where extensive compound curves are required. However, they are not cost/time effective for the Long-EZ Their production cost is high due to mainly tooling amortization, reject rate and packing requirements.

To say that pre-molded fuselage shell would significantly reduce building time is not true. Effect on total building time is less than 3%.

Long-EZ Fuselage Shells

Time Savings - Man Hours

Chapter 4	-5 mh	Round bulkheads
Chapter 5	+15 mh	Fab and glass sides
Chapter 6	-8 mh	Exterior jig required
Chapter 6	+10 mh	Carve and glass bottom
Chapter 7	+13 mh	Carve and glass outside.
Total	25 mh saved - 2.5 percent	

Fuselage shell cost, including packing and shipping $500 - more than materials for moldless construction. Results = $20/man hour.

SHOPPING

Aircraft Spruce has come up with a really nice placard sheet. It is black vinyl with white printing on it, and a sticky back. It has just about everything you will ever need to label your instrument panel. They have printed each item four times so if you ruin any you have some spares. You can cut them out of the sheet with scissors, peel off the back and stick the label in the appropriate position on your panel. There is even a complete checklist and a passenger warning sticker.

Lycoming O-235 1600 SMOH, 800 STOH in storage new crankshaft and cam at major overhaul.

Call: Bill Clark

(301)889-5092
(301)256-5671 (after 6pm EDT)

Lycoming O-235-C1 0SMOH, new crank, new cam, new bearings, chrome cylinders, fuel pump. Zero time, slick mags. Modified for 100 Oct. $4000 plus shipping.
Call: Charlie Gray,
(305)822-5040

Continental C-85-8. Fresh overhaul, 6 hours run in time. New Slick mags and harness.
Contact: Joe Moore,
11320 Hubbard Rd,
Grass Valley, CA 95945
(916)265-4952

Lycoming O-235-L2C factory remanufactured engines specifically set up for a Long-EZ. They include fuel pump, MA3PA carb with accelerator pump, oil screen and slick mags. Also has new Lycoming engines to your specification.
Contact: Norm Bender
804 Meadow Lane
P.O. Box 30343
Memphis, TN 38130
(901) 365-6611

Six Continental O-200-A engines for sale.
Contact: Rudolph Spremich,
520 Turquoise Street,
New Orleans, LA 70124

Dick Waters of Florida can supply Lycoming engines to suit your requirements, and is also working on an accessory case to accommodate a mechanical fuel pump. This will be very useful for builders who have engines without fuel pumps.

An Original VariEze main gear strut for sale. $195 and also several other VariEze parts.
Contact: Wm. C. Morgan,
6295 White Mill Rd. Rt #3,
Fairburn, GA 30213

Shopping at RAF.
The following items are available from RAF. Tie Tacs and Charms - Silver and Gold - $6.50. These come both VariEze and Long-EZ.

Belt Buckles, VariEze and Long-EZ, VariViggen. These come large for guys and little for gals. Shiny or brushed finish. $20.00 each.

Three ship poster of the Defiant, VariEze & VariViggen. $2.75 each or $5.00 for two plus $1.00 postage.

We try to keep in stock a selection of the Canopies which are for pick up at RAF only. If you give us approximately 2 weeks we usually can get the color you need.

Clear canopy	$199
Green canopy	$229
Smoke or Bronze	$249

Main Gear $309 and Nose Struts $55.55.
We still have a lead time of 7 to 8 weeks. Because of trying to get the gear shipped as soon as possible, please send your payment with your order. We will hold your check until your gear is shipped. If you are going to pick the gear up here at RAF please do so within 2 weeks as we have a storage problem and if you do not need your gear we will joggle your name back down the line. We have so many people needing their gear that we do not feel that we can hold the gear for an indefinite period of time.

Video tape - Building the Rutan Composite.
This tape runs for 96 minutes and covers every phase of construction. The tape comes in either VHS or BETA $49.95 plus $4 for postage.

Resin/Hardner Storage.
Several builders have reported that their resin or hardner or both have settled out or crystallized. Do not use your resin or hardner while is is in this condition. This problem is caused by temperature cycling. Never keep your resin or hardner in a cold place or on a cold cement floor. It should be stored up on a shelf at room temperature. If you see your resin or hardner start to crystallize and settle out, is it important that it be returned to it's normal clear state as soon as possible, even if you don't plan on using it right away.

To return crystallized or separated resin or hardner to it's normal state, place the jugs (caps on tight!) in hot water (160 F to 190 F) until the crystallized material goes back into solution. Be patient, and occasionally agitate the jugs. The longer you leave the jugs in hot water, the less likely this is to occur again. Depending on how badly the material gas crystalized the process could take 30 minutes to 3 hours.

If after 5 hours at 160 F - 190 F your resin or hardner has not become clear, return it to your distributor. Once it is clear and provided you store it at room temperature, it should remain clear, and the structural qualities of the epoxy will not be impaired.

Questions: I have built part of my aircraft using Safe-T-Poxy without checking my ratio pump. I now find that the pump is for the older epoxy with 20:100 ratio. What now?

Answer: You must discard all parts built with the wrong ratio. Epoxies should be mixed as accurately as possible. Errors as much as 10% can be accepted but definitely no higher. Structural integrity, particularly long-term will be unsatisfactory with the enormous error in ratio you have been using. Note that it is a good idea to occasionally check the delivered ratio of your pump. Check that the

valves are clean. You can modify the ratio of these pumps by drilling a new pivot hole for the handle. If the pivot is moved to the left the ratio of hardner to resin is increased. The 20:100 pump will deliver 43:100 if the pivot is remote, about 30 inches to the left of the pump. If you use a remote pivot be sure to clamp the pump base securely to the workbench and provide a stop to prevent piston over travel. (see CP #).

STICKING FUEL VALVE
Some VariEze fliers continue to have problems with their fuel valves sticking. In CP 17 we reported that tight valves must be overhauled before flight. The brass valves can be fixed by dismantling, cleaning and installing a lighter spring (or cutting some off the existing spring). If this is not completely successful the valve must be replaced. In CP 18 we switched to a Weatherhead #6749 valve with a Delrin spool. This appeared to solve the problem. However, a few people still had valves that were hard to turn. Recently a VariEze had a forced landing due to fuel starvation. The airplane was damaged, but fortunately the pilot was not hurt. Examination of the valve revealed that the Delrin spool had broken internally and the valve handle would not turn the spool. This valve had become so tight, on one occasion it required pliers to turn. This VariEze should have been grounded for valve overhaul.

CAUTION If your VariEze fuel valve (brass or Delrin) takes more that 5 lbs. of force to turn it, (10 lbs. is ok for long-EZs) ground your airplane until this is fixed.

The best fix is to shorten the spring by cutting some off and lubricate the valve spool and body with Parker fuel lube. (as reported in CP 25, page 5). Do not treat this situation lightly, you could destroy your aircraft for lack of fuel and yet have plenty of fuel on board.

CAUTION

There is some bad information circulating around about painting styrofoam with Latex house paint before glassing. This is totally false, and should not be done under any circumstances. The foam is there not only to give the correct shape to a part, but to provide buckling support to the stressed skin structure. In order for this support to be adequate, the glass skins must be bonded very strongly to the foam core. If you have a coat of house paint between the glass skin and foam core, this bond cannot be any stronger than the coat of paint. This is a serious structural problem and could very easily lead to a structural failure. If you have built any parts using this method, consider these parts unairworthy, and discard them.

Rebuild them using the correct method, as described in the plans.

CAUTION!
We are getting an alarming number of calls from builders asking questions that have been clearly answered in a previous newsletter. The information contained in the CP is more important than the plans, since it is more current.

When you receive your CP, read it very carefully, and read all of it, not just the plans changes. Jot down comments, builder hints, etc. on

the appropriate plans pages, and of course all plans changes must be written into your plans.

Remember, the only way we at RAF can get updated information, plans changes, or mandatory safety changes, to each builder, is through the Canard Pusher newsletter.

NEW TIRE TESTED
We recently tested a neat 6 ply tire for both VariEze and Long-EZ which is a little larger than the 3.40 x 5 Goodyear tire, but looks just exactly like a miniature 500 x 5 aircraft tire. It has a smooth rib pattern and is rated to 70 lb./in. We have a pair on N79RA, together with a pair of the current small wheel pants, and we like the tire, and recommend it for all VariEzes and for those builders of Long-EZs who do not want to use the larger 500 x 5 tires.

This new tire should be available through Aircraft Spruce and Wicks Aircraft. It is an 11" x 400 x 5 6 ply ribbed tire. Be certain to use only the 6 ply rated tire.

Mismatch on the Main Gear
Due to a mold shift, a few Long-EZ main gear struts have been shipped with a slight mismatch. We inspect every strut and have determined that a mismatch of up to 0.1" is of absolutely no concern structurally. You can sand the surrounding glass down to match, or you can build up the low spot with strips of UND and Safe-T-Poxy. Either method is acceptable. A disc grinder with a 16-grit heavy duty disc is best to remove the flash. Be sure to wear a dust respirator and protect your skin with Ply-9 to prevent itching. **SKETCH OMITTED**

ADDED CRUISE EFFICIENCY CHART
The Long-EZ Owners Manual cruise fuel flow chart plots fuel flow vs. indicated speed (in knots) with lines of altitude. The chart below may be more handy in flight planning and can be added to your Owners Manual. **CHARTS OMITTED**

PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category Definition

MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LONG-EZ PLANS CHANGES

LPC #65, MAN GRD
There are indications that the back injury noted on accidents (pg 3) may have been caused by the center speed brake diagonal being forced through the seat back after failure of the landing gear and the airplane's belly impacted the ground. Refer to the sketch and remove the portion of the plywood bulkhead (part #LB9) shown to allow it to collapse without piercing the seat bulkhead. Double check that the speed brake arm (#LB20 & #LB2) does not go over center with speed brake down - recheck the 40 lb. closure force. **SKETCH OMITTED**

LPC #66, MEO
CP #28, Page 9, LPC #61, the part #6083 should be #60883.

LPC #67, MEO
Section I Page5-3, nuts on the AN6-80A bolt should be AN363-624, not MS21042-6.

LPC #68,MEO
Section I Page 4-1, note at the foot of the page. Remove "NOT" so that it reads, "micro slurry is used on this type R45 foam. We do recommend slurry to be used on all of the various foams in a Long-EZ.

LPC #69, MEO
Section IIL, Page 14, Conical engine mount. The 7/8" O.D. x .049 cross brace tube must be moved down in order to clear the fuel pump. It is shown in the correct position on page 15.

LPC #70, MEO
CP #28, Page 8, under builder hints, UND layups on the fuselage sides should be + 30 not + 45. This is shown correctly in the plans.

LPC #71,MEO
Section I, Page 2-1, add to Ken Brock parts list - 4 spacers A4-84 and 2 nuts J1.25 (axle spacers and nuts).

LPC #72, MEO
Section VI, Landing Brake Page 2, part number LB10 should be changed to make the "ear" 1/2" longer to avoid interference with LB3. If you

bought this LB10 part from Ken Brock, this change has already been accomplished. **SKETCH OMITTED**

LPC #73, DES
Owners Manual checklist page 66. After "canopy-locked" add "visually confirm proper canopy latch engagement and proper safety catch engagement".

LPC #74, DES
Owners Manual Page 47, add, CAUTION prop bolts - recheck torque (180 in.-lbs.) before next flight when a transition is made from a wet climate (high humidity) to dry conditions. Wood shrinkage in dry environment can loosen prop bolts and result in flight loss of the entire propeller.

VARIEZE PLANS CHANGES.

See LPC #65
This applies to VariEze as well.

Owners Manual, Page 38.
Add CAUTION prop bolts - recheck torque (180 in-lb) before next flight when a transition is made from wet climate (high humidity) to dry conditions. Wood shrinkage in dry environment can loosen prop bolts and result in inflight loss of the entire propeller.

COMM ANTENNAS - VARIEZE.

The Comm antennas that mount on the landing gear can break after some time in service. This is because most builders apply the copper foil to the underside of the strut. The strut flexes and bends under taxi and landing loads and will eventually fatigue the copper foil. This can be prevented by attaching the copper foil to the leading edge of the strut.

Larry Lombard installed an excellent loop-type comm antenna in his VariEze. It is made from 1/4 inch wide copper tape. It is a full loop antenna, and has no ground plane. This copper foil should be installed per the sketch below, and ideally you should start

---

out with it about 102 inches long, and, using a SWR meter, optimize it by trimming it off in small increments. Larry's is approximately 99" long, but this may vary slightly from airplane to airplane and radio type. It is important to orient the copper foil as vertical as possible on each side, then let it form a "V" under the top cover and a "W" on the floor such that it clears the nose wheel well. A short piece of RG58-AU should extend from your radio to the fuselage side at approximately the mid point vertically. Solder one end of the copper foil to the center conductor of the RG58AU and the other end of the copper foil will solder to the shield of the RG58AU (after checking the length). Put one ply of light weight fiberglass or BID over the foil to protect it from damage, and you will have an excellent drag-free comm antenna.

SKETCH OMITTED

LONG-EZ BUILDER HINTS
Several builders have enquired about using the Rolls Royce 0-240. We have never tested this but it should be an excellent engine for the Long-EZ. It is certificated for use as a pusher, it comes standard equipped with a mechanical fuel pump and weighs 246 lbs. complete with starter and alternator. The only drawback that is immediately obvious is that the induction system comes up over the top of the cylinders which will necessitate a blister on top of the cowl on each side. We should see one or two installed in Long-EZs within the next year or so, and we will publish any data we get in future CPs.

A cheap automotive battery cable terminal cleaner (approximately 85 cents) makes an excellent foam carving tool, and works great in small corners.

Small sanding discs made by Merit Abrasive Products, Inc, P.O. Box 5448, Compton, CA 90224, work very well on a dremel tool. This company sells holders and sanding discs and calls them 1 1/2" diameter power lock holder and disc.

When you Bondo your wing jigs to the floor, be sure to Bondo them so that you can remove the bolts and spit the jigs vertically or you will not be able to get the foam cores into the jigs.

If you elect to use Rochester electric gauges, be sure to run a separate ground wire from all the electric gauges to the firewall. This will assure accurate, non-fluctuating indications. Simply hook all the electric gauges ground terminals together and run one 22 ga. wire from the instruments to the firewall or engine.

On the centersection spar caps and wing spar caps, most people will require the extra plies as called out in CP #25 and CP #28. If you are going to need the extra plies, it is best to apply them in order. That is, the longest ply should go on first, and the shortest ply should go on last.

CLARIFICATION
Section I, Page 4-2. Several builders have had difficulty understanding the sketch of the aft seat bulkhead. This sketch shows a 0.95 taper in the left side. Since this is a symmetrical part, it follows that there is also a 0.95 taper in the right side. This fact is verified by the dimensions shown. **SKETCH OMITTED**

Vince Golden (Long-EZ builder) sent us a really neat homebuilt hot wire alternative to the Variac. Vince built one and sent it to us and we have been using it for a couple of months and find it to be excellent.

Part required:

1 Hardware store dimmer switch	$4.59
(We used an 'ener-g-save' push on/off single pole)	
1 Capacitor .22UF 200 VDC	.35c
1 Resistor 220 OHM 1/2W	.20c
1 Transformer 28 VAc 4 Amp Tranex 24-10024	$7.50
	$12.64

You will have to modify the dimmer switch, by installing the capacitor and the resistor inside the dimmer switch box. This will also give you the ability to run a single speed dremel tool as a variable speed.

Wiring Diagram **SKETCH OMITTED**

Dimmer Modification **SKETCH OMITTED**

Note! By disconnecting the transformer the dimmer can be used to run a dremel or electric drill.

BID TAPES
There is still some confusion as to what BID tape is and where and how it is used. BID tape in not a purchased item. You can not buy a roll of BID tape. You cut it from your 38" wide roll of BID glass. BID tape should be cut in 2" or 2 1/2" wide strips at 45 degrees to the selvage edge. In most places where you will use BID tapes (eg. fuselage sides to bulkheads) you need to lap 1" onto the bulkhead and 1" onto the fuselage side. Therefore you need a 2" wide tape. In actual practice it is wiser to cut the tape 2 1/2" wide, because it will stretch and get narrower between the cutting table and the airplane.

If you need a longer BID tape than you can cut off a 38" wide roll, it is ok to join the tape by lapping 1/2".

Since you cannot squeegee the BID tapes very easily you should wet them out with a brush, then peel ply the edges to give a neat smooth finish and also to help dry out the layup. Add a minimum of epoxy to wet out the peel ply, rather use the peel ply to soak excess epoxy out of the BID tape layup. Always peel-ply all edges of tapes.

VARIVIGGEN NEWS

Leonard Dobson of Georgetown, Texas, has his Viggen finished and it is absolutely gorgeous! See photo. "Dobby" reports that he started construction July 1978 and has invested approximately $16,000 and 5000 man hours! While in the final sanding stages he felt like he was cleaning an elephant with a tooth brush! Anyway Dobby, congratulations on completing your Viggen, sure hope you can get it to Oshkosh.

Ken Winter of Tulsa, Oklahoma, reports that he should be at Oshkosh with his Viggen, which at last report was complete except for final engine control hookup.

Arthur Schwartz has over 65 hours on his Viggen now and reports that he will be at Oshkosh. Arthur is having lots of fun visiting different airports.

Gene de Ruelle has started working again on his Viggen project after a period of inactivity, and he reports finding a Cessna 150 flap motor and jackscrew, which has worked out real well for his reflex. The unit came complete with wiring and limit switches and a pivot mount that is

a perfect fit. Gene got his from San-Val parts in Van Nuys, CA. and paid $54 for it. See photo. Gene is building his verticals now, and reports that Jesse Wright's kit is really a big help.

My Viggen N27MS is still running like a dream, the only problem encountered has been a bad magneto coil in one Bendix mag. I am presently overhauling the mag and just generally giving the "old girl" a good inspection in readiness for the annual cross country to Oshkosh. N27MS first flew in September 1977, that makes her almost 4 years old with just over 500 hours.

Hopefully this will be the first year that we have had more than one Viggen at Oshkosh, and we have a possibility of as many as three. Sure would look great to see a flight of 3 Viggens in the pattern!

For Sale: VariViggen project. 1st Edition plans with all updates, Spruce kit, fiberglass parts, wing attach fittings, Cleveland 500 x 5 wheels and brakes, master cylinders and brake pedals. Will trade for Long-EZ plans and parts.
Contact: Ron Lorimor
1909 Rock Street #6
Mt View, CA 94040

LONG-EZ

FAST - EFFICIENT - HIGH UTILITY - LONG RANGE

Long-EZ N79RA with 75 gal. back seat tank during the world distance record flight. **PHOTO OMITTED

THE AIRPLANE
The Long-EZ is a small, high-performance, high-utility homebuilt sportplane. While recommended mainly for Day-VFR operation, competent

pilots can also equip it for night and IFR flying. Power plant is either the 0-235 Lycoming or the 0-200 Continental. It has an alternator-powered electrical system and can be equipped with electric engine starter. It's cockpit layout is designed to compliment pilot work load, with throttle, mixture, carb heat, pitch trim and landing brake controls on the left console and side-stick controller on the right console. Seating provides correct armrest, lumbar, thigh, and headrest support allowing "recliner-chair" comfort not found in conventional aircraft seats. This allows long, fatigue-free flights. The inboard portion of the large wing strakes are used as baggage areas, accessible from the front and rear cockpit. These, combined with special suitcases and three other storage areas, provide nearly 10 cubic feet of baggage room.

The airframe structure is a sandwich of high-strength fiberglass facings with a core of rigid closed cell foam. Extensive use is made of the new type R45 P.V. core foam. (poly vinyl). The facings are laid up directly over the shaped core, thus expensive tooling is not required. Flying surfaces are full-core reducing complexity, increasing contour stability, and improving corrosion resistance. As compared to conventional metal or wood, composite sandwich structure offers less construction time, more uniform stresses, improved fatigue life, better environmental resistance, and increased surface durability.

TRAVELLING MACHINE

At last, an airplane that is specifically developed for efficient, high speed, long-range travelling with room for two adults and plenty of baggage. Fuel allowance with two adults is 38 gallons. Single-place, you can carry 52 gallons! If you're in a hurry, you can cruise at 75% power at 8000 ft at 185 mph (161kts), burning 6.51 gallons per hour. This will take two of you from Los Angeles to Seattle or Chicago to Daytona Beach non-stop (965 miles), in 5.2 hours with a 40 minute fuel reserve. If you're not in a hurry, you can cruise "economy" at 12000 feet at 144 mph (125 kts), burning only 3.52 gallons per hour. This will take two of you from New York to Dallas non-stop (1430 miles) in 10 hours with a 40-minute fuel reserve. Single place, using the entire 52-gallon fuel capacity, stretches the maximum range and endurance to over 2000 miles and 16 hours!

The high efficiency, long-range capability increases a pilots options for fuel availability and weather detours. The fact that the Long-EZ can carry the same load and fly as fast as other 160-180 horsepower aircraft, means large fuel savings - 29 mpg at fast cruise, 41 mpg at economy cruise.

UNUSUAL EFFICIENCY

The Long-EZ uses the very latest aerodynamic technology, combining winglets, a high aspect-ratio wing with Eppler airfoils optimized for efficient cruise, and a configuration with far less wetted area than conventional airplanes. As a demonstration of its efficiency, our prototype with a large rear-seat fuel tank flew over 4800 miles, setting a worlds distance record, and landing with enough fuel to surpass 5000 miles. At that, it's capability was not taxed - it's initial climb rate was over 600 ft/mn! At light weight, it climbed to 27000 ft in still air - an altitude unheard of for a fixed-pitch, non-turbocharged airplane. Our Long-EZ is so efficient, the engine can be

shut down while at 5-ft altitude over the numbers at only 120 knots, then it can pull up, fly at 360 degrees pattern and land on the same runway - completely without power! It's power-off glide angle is only 3.7 degrees - thus a belly-mounted drag devise (landing brake) is used for landings.

SUPERB FLYING QUALITIES
Development of the Long-EZ included flight testing of many refinements to optimize flying qualities. It is a very solid, stable airplane that has responsive ailerons, good turbulence response, excellent "hands-off" stability and safe stall characteristics. It can be maneuvered sharply, even to full aft stick, without fear of stall or spin. Flight tests show the prototype to be free from stall departures and spins for all types of entries, including tailslides. Climb is excellent, even at the full-aft-stick speed.

Trim changes due to power, gear retraction or landing brake are all very small. It's wide cg range allows a large range of pilots or passengers weighing up to 240 lbs.

The Long-EZ's approach and landing speeds are 75 mph (65 kts) and 60 mph (52 kts) at normal landing weights. The approach and landing are docile and conventional. Forward visibility is excellent even during a "full stall" touchdown - a considerable improvement over our earlier VariEze.

THE HOMEBUILDER SUPPORT
The Homebuilder support. The plans are a literal education in using the materials and is a detailed step-by-step guide to construction using an illustrated format not common in aircraft plans. The Rutan newsletter, the "Canard Pusher", published since mid 1974, updates plans, provides building hints, etc. Complete owners manual provides all necessary information for safe initial testing and for normal and emergency operations.

THE TEST PROGRAM
The test program was probably the most extensive and successful ever conducted on a homebuilt. It included basic flight tests for flying qualities, performance and systems, spin and dive test to FAR part 23 requirements, static load tests and landing gear drop tests exceeding part 23 criteria, environmental/thermal tests on structural materials/components, manufacturing methods testing, and many others.

COST AND BUILDING TIME
The complete package of raw materials available from the two distributors listed, including all fiberglass, epoxies, foams, fillers, sheet metal, tubing, hardware, control system materials, VFR instruments, plumbing, tools, tires, wheels, brakes and upholstery (cushions and special suitcases) costs about $2,900. Any of these items can be purchased separately. We strongly recommend that you get the distributor's catalogs to familiarize yourself with the materials. A complete bill-of-materials is in the plans.

The S-glass roving molded structural fiberglass main gear and nose gear are available from RAF, at $277.95 and $49.75 respectively. Many other prefab parts ranging from propellers, cowlings, canopies and welded engine mounts to small aluminum brackets and bushings can be purchased

from the listed manufactures. All those prefab parts cost approximately $1,600 - and using them, the competent builder can build a Long-EZ in as little as 800 man-hours. The budget-minded builder may elect to build most of these prefab parts himself, using the drawings in the plans. His building time would exceed 1500 hours and he would save most of the above cost of the prefab items. Contact the manufactures for their catalogs showing available prefab parts. These are also listed in the plans bill-of-materials.

Engine costs vary widely. Our prototype has an 0-235 Lycoming that had 1400 hours, when purchased for $1500. It has 600 hours to overhaul and will be worth then, about what we paid, thus this is a very economical way to go. Newly overhauled or new engines can cost from $3000 to $6000. Engine accessories, such as instruments, prop extensions etc cost about $300 to $500. In summary then, total cost can run from $5300 for a basic airplane with a 3/4 runout engine and owner-built prefab parts, to $9900 for everything available purchased and a zero-time engine. IFR avionics can add from $2000 to $15,000 to those numbers, with many options available.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 30. If you are building a VariViggen from 2nd Edition plans you must have newsletter 18 through 30. If you are building a VariEze from the 1st Edition plans you must have newsletters 10 through 30. If you are building a VariEze from 2nd Edition plans you must have newsletter 16 through 30. If you are building a Long-EZ from 1st Edition plans you must have newsletter 24 through 30.

A Current subscription for future issues is mandatory for builders, as this is the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave CA., approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to fly-ins. When arriving at Mojave by car turn east at the Carls Jr restaurant to find the airport.

When writing to RAF always send a stamped, self-addressed envelope along if you have questions. If you are making an order, its best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed your reply.

Annual Workshop/Seminar at RAF
The workshop.seminar this year will be on Saturday 28th November 1981. It will consist of a seminar by Burt Rutan and Mike Melvill from 9:00 am to 10:00 am. Flight demos from 10:00 am to 11:00 am. We will show our construction video tape at 1:00 to 2:30 pm and have question and answer from 2:30 to 4:30 pm.

Please bring folding chairs if you can. Lunch will not be served at RAF, but we will try to transport you to the "fast food".

RAF Activity
Since the last newsletter has involved; the Oshkosh convention trip, builder support, development of our RAF Model 77 sailplane, engineering

flight tests of our RAF Model 73 jet, flight tests of the RAF Model 68 Amsoil racing biplane, design of the RAF Model 78 and 79 commuter airliner for NASA wind tunnel testing, flying for several TV programs, laminar-flow flight measurements, flight demos, construction demos, and preparing a video tape to illustrate the flight test preparation of a new Long-EZ.

RAF Aircraft on the tube
Some very spectacular footage of Long-EZs, VariViggen and Defiant has been shot this summer and fall for several scheduled TV programs to be aired this fall probably during November.

1. OMNI Science Series - network depends on area, generally at 7:30 P.M. Saturdays - 10 minute segment of spectacular formations, aerobatics and remote mounted cameras.

2. Whats up America - scheduled on Cable TV - segment on Homebuilts - much of it Long-EZs at RAF.

3. Guinness Book of Records - segment of Dick and Jeana's Long-EZ shot flying up the face of Angel Falls in Venezuela, South America.

Long-EZs are flown extensively
While the average homebuilt airplane is flown less than five hours per month, the high-utility Long-EZs are proving to be quite an exception. Based on reports from the Long-EZs now flying they are logging an average of 30 hours a month. The first five Long-EZs to fly logged a total of over 900 hours flying in their first six months of operation!

Video Tapes available from RAF
We are pleased to announce the addition of a new video tape. This tape was premiered at Oshkosh '81 and was made by Ferde Grofe. It is called "Go-a-Long-EZ" and we sell it here at RAF (VHS or BETA) for $49.95 plus $4.00 handling and postage. Go-a-Long-EZ is an audio-visual presentation of the subjects covered in Appendix I and Appendix II of the VariEze and Long-EZ Owners Manual: Preparation for initial testing, including weight and balance and initial flight testing. We also have the building seminar tape called, "Building the Rutan Composite". This tape sells for $59.95 plus $4.00 for handling and postage. Both of these tapes were shown daily at Oshkosh and proved to be very popular.

EZ Clubs
Charlie Gray of Miami Lakes, Florida, has formed a group of VariEze/Long-EZ builders in the South Florida area. This is a very active group and have had several meetings already. Next meeting is at Charlie's house on Saturday, October the 24th. This is a "minimeet" and the next major meeting is December the 5th, time and place to be announced. There were 52 people present at the last get together, so you can get some idea of the size of the operation. Charlie has been out to RAF several times in the past six months and is doing a tremendous job, not only organizing this South Florida group, but helping builders with construction problems. He is building 2 Long-EZs and is quite far along with both of them. Charlie has put out a newsletter, Eze Builders of Florida, that contains some useful builder hints and also covers the meetings. Write to Charlie Gray, 6893 Seagrape Terrace, Miami Lakes, FL 33014.

Art and Bonnie Lazzarini, P.O. Box 1691, Hailey, ID 83333, phone (208)788-3453, requested us to publish their names and address in the CP in hopes that other EZ builders in Idaho might make contact, perhaps share a beer and some moral support.

RAF Conducting Instrumented Flight Test Program
For A Major Aerospace Firm
The new aircraft is a scaled flight demonstrator for Fairchild Republic's proposal for the Air Force's Next Generation Trainer (NGT) program. The full scale NGT, designed by Fairchild Republic is a two-place, highly fuel efficient, twin engine turbofan trainer intended to modernize the Air Force T-37 fleet.

In early 1981 Fairchild Republic contracted Ames Industrial Corporation to design, build and test the scaled flight demonstrator. Fairchild supplied accurate loft of the external shape of their NGT design. Ames hired Rutan Aircraft Factory to design the structure and systems and to conduct the flight test program. The scaled demonstrator is 62% of the size of the full scale aircraft.

Ames previously built the Rutan-designed AD-1 skew wing jet aircraft for NASA in 1978. The prototype scaled NGT construction effort, took seven months. The aircraft was shipped to Rutan Aircraft's facility in early September. After a six day flight preparation, the first four flights were flown within a 48 hour time period. The aircraft's maintenance availability and flight reliability have been flawless. All flights completed the planned objectives with no mission aborts. All instrumented stability tests (except spin and airload flights) were completed within a two week time period. The aircraft is now being fitted with an anti-spin parachute system and strain gauges to measure flight loads.

Flight tests to date have shown the Fairchild configuration to have the excellent flying qualities required for basic military flight training. Despite the small size of the demonstrator (1,500 lbs. gross weight and 21.8 ft. span), its handling qualities permitted the first four flights to be flown by four different pilots, one having no previous turbo-jet experience.

The flight demonstrator was instrumented by Flight System Inc. Data flights include telemetered stability and control parameters to verify the calculated and wind tunnel measured engineering information. The use of the manned, scaled flight demonstrator produces higher quality data than other methods, particularly for areas such as spin susceptibility and spin recovery. The scaled flight demonstrator was built within a schedule and cost framework that compares in scope to conventional wind tunnel programs. However, the added benefits of dynamic stability data and pilot qualitative information result in considerable improvement in the findings.

The structure of the scaled prototype is composite sandwich using oriented uni-directional carbon fiber or fiberglass for facings and spar caps and rigid closed cell foams for core. The fabrication method

is the moldless procedure with full core flying surfaces as developed for previous Rutan-designed aircraft such as the VariEze, Defiant, Long-EZ, Quickie, AD-1 and Amsoil biplane racer. Like the AD-1, the scaled NGT is powered by two Ames TRS-18 turbojet engines.

RAF hopes to conduct a similar scaled demonstrator test program on our Model 78 commuter airline design. See the October '81 issue of Sport Aviation for a 3-view of the Model 78.

NASA Tests Long-EZ

Researcher Bruce Holmes and Research test pilot Phil Brown of NASA's Langley Center recently visited RAF to study the Long-EZ. Of particular interest was the measurement of the extent of natural laminar flow on the flying surfaces. Also, the stall characteristics and departure susceptibility. They had previously measured extensive laminar flow on their full scale VariEze in the Langley 30 x 60 wind tunnel. This was verified by flight tests at Langley of Bob Woodalls VariEze. They found essentially textbook predicted boundary layer transition locations are being achieved with the airfoils on the EZ despite the presence of wing sweep and canard impingement. This is due to the stable contour that is achieved with our full core composite construction.

The Long-EZ main wing airfoil was designed by Richard Eppler. It has a steep initial pressure gradient intended to provide a reasonable probability of laminar flow despite minor leading edge contamination. The Eppler computer code predicts 32% chord laminar flow on the upper surface for a perfectly smooth surface. As the photos elsewhere in this newsletter show, the sublimating chemical tests on Long-EZs N26MS and N79RA verify that the wings are achieving the full 32% chord laminar flow. Small insect remains on the leading edge forward of about 4% chord will not trip the boundary layer. Bugs aft of 5% chord will destroy laminar flow, as will the small bump of a paint stripe. We now have documentation of the boundary layer characteristics on all surfaces and intersections of the Long-EZ.

Also of interest to NASA was the departure immune stall characteristic we have noted during our tests. NASA wanted to test the spin susceptibility to supplement the extensive data they have gathered on all types of general aviation aircraft. Phil put the Long-EZ through all types of extreme stall entry conditions: accelerated entries, vertical entries, etc. with all combinations of control inputs. He also alternated left and right rudder inputs at the dutch roll natural frequency, combining opposite aileron to add adverse yaw effects, at the maximum attainable angle of attack. Despite all combinations of gross misuse of flight controls, and attaining over 45 degrees sideslip, he was unable to obtain a departure from controlled flight. Phil left with the comment that he could find no way of inducing loss of control in the Long-EZ.

This is a stark contrast to the general aviation aircraft configurations he has testing at Langley, all of them being relatively susceptible to loss of control or spin entry from any aggravated stall entry. Many of them have unrecoverable spin modes that require wingtip rockets or anti-spin parachutes to effect recovery.

Oshkosh Trip

RAF took four airplanes to Oshkosh this year. Burt and Pat flew in the Defiant (N78RA), Larry Lombard and his wife Janet took the prototype Long-EZ (N79RA), Sally and son Keith flew in Long-EZ (N26MS) and Mike and his mother Isobel flew the VariViggen (N27MS).

Mike and Sally departed Mojave early Thursday morning and flew via Las Vegas to St. George, Utah, where the Viggen had to land for fuel. While Mike was getting gas, Sally and Keith remained at 9,500 ft. and circled. As the Viggen took off from St. George and climbed back to join up with Sally, the Defiant and the prototype Long-EZ arrived having left Mojave 30 minutes after Mike and Sally's takeoff. We flew as a flight of four for awhile, then Burt decided to go on ahead and check weather, so he and Larry pushed it up and slowly pulled ahead. We were always in radio contact, even as Burt and Larry were descending to land at Aspen, Colorado.

Sally and Mike arrived at Aspen some 30 minutes later and Sally proceeded to make Mike look bad by landing in half the distance and making the first turn off!! Burt decided that it was really too late to continue (it was only 11:00 A.M.!) so we tied the four planes down and went into town, where we spent a most enjoyable afternoon and evening. What a super place.

Next morning all four aircraft departed early, even so the density altitude was 10,800 ft. so Mike decided to transfer his mother into the Defiant for this leg. The Viggen got off ok, but rate of climb was down to 200/300 fpm. Both Long-EZs and Defiant got off and climbed well. We proceeded to Kremling VOR and then east over the Divide west of Boulder. We flew pretty much as a four ship until we started to run into a broken undercast. Burt and Pat went ahead in Defiant and found some holes and decided we should all land at Hastings, Nebraska for lunch. After lunch, Defiant headed out, while Larry, Sally and Mike flew in a three ship as far as Bascobel, Wisconsin, where Mike and Sally landed to fuel the Viggen. Then on to Oshkosh.

As you know by now. Oshkosh was bigger and better than ever. A number of Rutan Aircraft flew in during the week and Irene Rutan's "official" count was:

VariEzes -	58
Long-EZs -	5
VariViggen -	2
Defiant -	1

John Benjamin's "Plane Vanilla" Eze (N40EZ) from Lancaster, PA won the designer's award. Don Jones, from Knoxville, TN received the runner up award for his excellent Eze, N300J.

It was a particular treat to see Ken Winter at Oshkosh. He flew up from Tulsa, Oklahoma, in his new VariViggen N31WW. It was so new, it still had a few unpainted panels but that did not keep him from flying it virtually every day in the fly by pattern. Ken and Mike flew in formation, quite a land mark occasion, since this was the first time two VariViggens had ever been in the air together, although 1981 was the 10th consecutive year that a single Viggen had been in attendance.

Five Long-EZs were at Oshkosh this year, two of them were also at Oshkosh 1980, N79RA, the prototype, and N21VE, Johnny Murphy's Sweet

Music. This year Mike and Sally's N26MS and Dick and Jeana's blue renegade N169SH were there, and on the first day of the show, Dan McElroy flew in from Seattle, WA. This Long-EZ is a story in itself. Dan had completed the plane exactly one week before Oshkosh, flew off the hours, got it signed off, and arrived at Oshkosh on schedule. Actually he only took delivery of his prefab fuel strakes from Task Research 2 weeks before Oshkosh.

All five of the Long-EZs have pilots of the fair set. Dan McElroy report that his wife Ellie made the third flight on their Long and also flew 2 of the 3 legs to Oshkosh. Johnny Murphy had recently checked his daughter out in his Long and of course you already know about Sally, Pat and Jeana.

Fred Keller was there from Anchorage, Alaska, with his Grand Champion VariEze, and it looked just like it had been taken out of the mold! Absolutely gorgeous.

The Annual Eze Hospitality Club dinner was held on Wednesday evening, and it will be held on the same day and place (Butch's Anchor Inn) next year. We had a nice big room, even a speaker system, and it is safe to say that about 150 persons enjoyed themselves thoroughly. We are all indebted to the Real George Scott for making all the arrangements and acting as master of ceremonies. Super job, George! Harold "Mule" Ferguson provided some good entertainment with his high class singing and his guitar picking.

The above report is from Burt's Mom, Irene, who did sterling work on the flight line, tracking down each Eze pilot, welcoming he or she and passing out the new Rutan Aircraft patches. We are indebted to both Mom and Pop Rutan for the excellent job they did at Oshkosh. Here is a list of the RAF type airplane and pilots at Oshkosh 1981.

Our aircraft returned to California separately as each was planning different routes to visit relatives etc. In all, counting Oshkosh airshow demos, our Mojave RAF aircraft logged 110 hours and 20,000 miles on the Oshkosh trip without mechanical problems of any type.

Design Origins of Quickie-type Aircraft
Because of the high amount of confusion on this subject lately, Burt has written an article that lists many facts not previously published. This article appears in the October issue of EAA's Sport Aviation magazine.

Mike and Sally's Long-EZ N26MS
Sally flew our Long to Oshkosh and back, put 37 hours on it and used only 1 quart of oil. We have 260 hours total time now, with virtually

zero maintenance. We could not be more pleased with the airplane. It does everything as advertised and more. Most of our flying is to and from work, which includes a lot of take-offs and landings. When commuting we only fly 0.3 hours between landings. I estimate we have well over 500 landings at this time, and the tires look as though they are good for that many again. I am very pleased with the 500 x 5 tires, we get excellent tire wear and a super comfortable taxi ride. With a decent wheel pant the performance is still excellent.

Sally and I recently made a cross country trip to Fort Collins-Loveland for the Rocky Mountain Regional Fly In. This trip was 720 nm (828 sm). We flew from Tehachapi to Loveland direct, non stop. This took us over Las Vegas, Grand Junction and Long Peak (14,300 ft.). Time was 4.9 hours, we burned 27 gallons of 100 oct. We indicated 120 knots at 13,500 ft. (temp. 1 degree C) for a true airspeed of 150.3 knots (173 mph). Our ground speed, block to block was 147 knots (169 mph).

Our figures for the return trip were virtually identical, I flew out there and Sally flew back. Weather was perfect with virtually no wind. The route took us over some spectacular country, with the highlight being perhaps flying over the top of Long Peak, which is on the Continental Divide west of Loveland. The Long-EZ performed flawlessly, and handled this kind of flying with absolutely no problems. It was comfortable, both in the front seat and the back seat. Our relief tubes worked well, and I am very "relieved" we put them in! Noise level, with headsets, was very acceptable and I must say it was nice to listen to taped music to pass the time. Here is a break down of the trip.

Climb segment: 4,000 ft. (Tehachapi) to 13,500 ft.
Fuel Used: 2.4 Gallons
Time: 0.3 Hours
Distance: 40 nm (46 sm)

Cruise segment:
Distance =720 -40 = 680 nm (782 sm)
Time =4.9 -0.3 = 4.6 hours
Ground Speed =680 =148 knots (170 mph)

4.6

Fuel used 24.6 gal Fuel flow 5.35 gph
Economy 27.64 nm/gal (31.8 sm/gal)

The Long-EZ Owners Manual shows 4.8 gal/hr at 120 kt indicated at 14,000 ft. (148 kt. true) at a gross weight of 1100 lbs. Correcting this to 1350 lbs. results in 5.4 gal/hr and 27.4 nm/gal.

Thus, on this trip our Long-EZ did slightly better that the Owners Manual, and certainly more than satisfied Sally and I. We won best composite at the airshow, and really had a great time.

Engine Oil Analysis
Gary Hertzler, owner of VariEze N99VE, has made arrangements with Spectro-Chem, P.O. Box 29074, Phoenix, AZ 85036 to do oil analysis for Eze owners at FBO cost price. Contact Lou Brand, and identify yourself as a Eze owner/pilot, and Lou will send you sample kits for $7.95 each in lots of 12 or more. The kits include a sample bottle and mailer.

You send a sample of your oil, attention Lou Brand, and in return you will receive an analysis sheet showing metal present in parts per million. Spectro-Chem has built up quite a history on aircraft engines, and can comment on your results with some authority.

This is an excellent preventive maintenance procedure and we thank Gary for setting this deal up so the Eze flyers can take advantage of it.

CP30, Page 3

Trimming the Aerodynamics of your EZ

Like any other aircraft, the trim and stability of a VariEze or Long-EZ depends on correct cg position and proper contour and incidences of all flying surfaces. There is an easy way to verify that your aircraft is rigged properly with the incidences correct. This involves flying at several airspeeds while monitoring the elevator position, then comparing your data with the design information. Measuring elevator position in flight is simple since the pilot can easily see an indicator attached directly on the elevator surface. If your EZ does not handle, perform and stall exactly as described in the Owners Manual it could be due to an improper incidence or contour of the wing, canard or elevator, and you should conduct the test below to see if your elevator is at the correct position. If the elevator position is not correct, your airplane may also have a large trim change when flying into rain.

Fabricate the plate and needle from .016 2024 aluminum. Paint the plate white and the needle black. Mount the plate to your outboard elevator fairing and the needle to the elevator (use 5 minute epoxy it will later peel off without damaging your paint job). Calibrate your elevator position (plus is trailing-edge-down) using your elevator position template from Chapter 11, page 6, making a mark on the white plate every 2 degrees.

Now, load your aircraft to the mid-cg position (99 for VariEze and 101 for Long-EZ). Fly in stabilized conditions, smooth air in level flight at 70, 80, 90, 100, 120, and 140 knots indicated. Plot your elevator VS speed data on the graph shown below. Your data should fall within the limits shown. RAF is interested to see the variations of this data occurring due to tolerances from one airplane to another. If you do this test, please send us your data whether or not it is within the limits shown. **SKETCHES AND GRAPHS OMITTED**

Low-profile Locknuts

The VariEze and Long-EZ extensively use the MS21042 locknuts. These are a high quality all metal aircraft approved type locknut. One builder has reported cracks in several of his MS21042-4 nuts during installation. Our tests have shown that we can torque these nuts to several times the recommended limits and even abuse them enough to round the flats without failure. We have seen no failures in service. If you have had any failure of these nuts contact RAF describing the conditions of failure, purchase date and vendor.

CAUTION: Nose gear shimmy can fail the nose gear fork.

Many of us operating EZs are lax on checking the friction of the shimmy damper during preflight. This is EZ to do since we do not see the nose

gear when parked nose down. Always check for the 2 to 4 lb. damper friction on preflight. If the damper is free, the gear can shimmy at high speed and fail the fork within 1/4 second. Further, the failed wheel can strike and destroy your prop.

Nose wheel rigged at the proper angle and having at least 2-lbs. friction damping cannot shimmy. Some airplanes have had a bent NG17 tube that binds under load. Then, the owner backs off and the friction adjustment to allow good taxi qualities. Then with little or no load (rebound) at high speed it can and will shimmy. If your gear pivot binds, making taxi turns difficult, check you NG17 for evidence of bending, or ovalizing. Some time ago we increased the wall thickness on the Long-EZ NG17 part sold by Brock to handle the heavier loads. If your NG17 is not perfectly straight, replace it with a steel tube of at least .125" wall.

One of the reasons that the shimmy damper can easily get out of adjustment is that to get the proper force, the spring is coil-bound or nearly coil-bound. Thus, if a little wear or a slight bolt back-off occurs, the damping action is lost. To solve this, Brock is now having made a supply of springs with a heavier (.083 diameter) wire. The orders filled after October will have the heavy spring. Also, as soon as they are received (mid November) Brock will be sending the heavy spring to all who have bought the nose gear assembly. We have tested the heavy spring on N26MS and have confirmed that the adjustment bolt can be backed off a full half turn before losing adequate damping friction. With the old spring a 1/8 turn would result in inadequate friction.

The shimmy failures have resulted in the rumor that the nose gear fork is not strong enough. This is not true. The failures were due to high speed shimmy, not overload. Our nosegears have been extensively tested to in excess of design ultimate loads (CP #18, page 4) and during punishing development tests of the rough field capability (CP #25, page 3). Also, the exact assembly is currently operating at higher weights (2,100 lbs.) and speeds (90 kts) in two jet aircraft, the NASA AD-1 and Model 73 NGT, without problems of any kind. Of course, the friction is checked during each preflight.

We strongly recommend that each Long-EZ and VariEze use the CP #25 spring shock in the nose system. This greatly relieves the shock loads experienced when encountering ruts, chuck holes etc.

Rudder Pedal Failure

There have been at least two cases of failure of the top tab which is welded to the rudder pedal, and to which the rudder/brake cable is connected. One case was a gas welded, homebuilt part, and this was attributed to a poor weld. Another case was a prefab Brock part, but according to the owner, the tab had been bent and then straightened cold. If this tab should fail, it will invariably fail while taxiing under braking load, when you need it most, and directional control will be lost.

As of this date (Oct 81) Brock-supplied rudder pedals have been modified per Figure 1, to strengthen the tab. If you purchased your rudder pedals prior to this date, you can obtain from Brock a pair of tab reinforcement brackets. Brock part #LE2026R-1 and LE2026R-2, and these must be riveted into place over the existing tabs per Figure 2. This will stiffen and back up the weld which failed. Of course, you can also homebuild these brackets from Figure 2. This is a mandatory change, see LPC #86. **SKETCHES OMITTED**

Six-inch Prop Extension
Last summer we learned from Rudi Kurth of Switzerland, Ed Hamlin and Bruce Tifft, that a longer prop extension spool would reduce the cockpit noise level and possibly increase performance. We collected accurate baseline data, then removed the standard 3-inch extension and installed longer ones. We have tested 4-inch, 5-inch and 6-inch extensions.

Most of our data was for the 6-inch extension. Results are as follows: As compared to 3-inch, sound level at pilot's station and rear seat was reduced two and a half to three DBA at high speed cruise and climb conditions. Oil temperature on all three airplanes tested with the long extension was increased. Cylinder temperatures on one of the airplanes increased. There was no measurable change in the performance of any of the airplanes due to extension length. We have been reluctant to recommend the long extensions because any change in the propulsion/drive system of an aircraft must be thoroughly tested for long-term durability. We now have a total of 300 hours 6-inch time on Long-EZs with no indication of problems, and since the two 8-inch extensions on the Defiant have run 600 hours it appears that no mechanical problems are indicated. Thus, if you can stand a 20 to 30 degree rise in engine temperatures you can, with a 1.5 lb. weight penalty, achieve a significant noise reduction by using a 6-inch extension. Note that we have tested this only with Lycoming engines and cannot predict the durability of a Continental application. Also note that since the Brock spinner mates to the front flange of the 3-inch extension, it is not as well supported when using the long extension. Brock is now developing an aft bulkhead for his spinner to provide firm centering support regardless of extension type.

From the Builders and Flyers
Eze builders if Florida.
Charlie Gray hosted a dinner for EZ builders on Saturday the 18 of July '81 at 7:00pm. Dinner was at "Beefsteak Charlies". We adjourned to Charlie's large home and six car garage in Miami Lakes. Betty Gray had coffee, sodas, and cookies for us. (Maybe Charlie figured out that if everyone got heavier, his two Long-EZs will be the fastest). Charlie led the group in a discussion of current Rutan developments, then discussed the formation of a club. He felt the purposes of such a club should be things like dissemination of builder's hints, where to buy tools and supplies, a flying group, and encouragement to those starting or completing their project. Mr. Gray's ideas were well received by the group and it appears we will organize during our next meeting.

The 35 of us broke up into three groups. Some people watched the RAF composite education tape in the living room. The rest of the group then either formed small bull sessions or went through Charlie's shop to look at his two projects and tools, supplies, etc.. Many good

questions came up in the shop so the flow of information was both diverse and extensive. The best part of the discussion was that there were pilots there who had finished their EZs, some close to finish, and many just starting along with a few just making up their minds. This led to more and better information coming out from diverse points of view.

The builders who were unable to attend missed a very fine evening. We started with Charlie G. giving each plans holder a folder with note pad and a large print of a delightful sunset taken by Charlie from aloft, we then ate a leisurely meal spiced with hanger flying and building. Finally we went and seriously talked about the costs, problems, and joys of EZ building. I hope those who did miss it are looking forward to the next meeting half as much as those of us who participated in the first meeting.

Robert Dunham
Florida

Jerry Gruber of Elkhart Indiana, has been building his Long-EZ since 7-5-81. As of this date Jerry is almost ready for primer and to cap it all, Jerry has never even seen a VariEze or Long-EZ in the "flesh". His own Long is the first. Jerry has built his own fuel strakes and judging by the photo he sent us, he is doing excellent work. Jerry will have light IFR instrumentation and should be flying in 4 to 6 weeks.

Susan Smale of Bakersfield, California, called today and her Long-EZ is in primer paint and she is wet sanding ready for the top coat. Susan is doing very good work and is hoping to fly in 3 to 4 weeks. Susan is one of 4 girl Long-EZ builders whom we have talked with, all of them are coming along real well.

Don Shupe's observations at the start of his third year, since he started building "Puff" back in July of 1976.
"I just looked up the original invoice from Aircraft Spruce for $2009.11 on 7/6/76, I've met a lot of fantastic people and had bunches of super experiences. I've seen the people associated with EZ's change too. In the beginning it appeared the EZ people were different than other people in aviation; different even from other homebuilders. They seemed to know what they wanted and dug in and did it. Not many were like the seven year builders I had seen so often with other homebuilts. Now I know that EZ people are different. There seem to be more aviators among us than among builders of other types of planes. We like to fly as much or more than we like to build. We like to talk, too, as much as anybody but, we like to fly more. Ed and Jo Ann Hamlin, Bernadette and "Puff" and I have flown together with "77EJ" probably more than 150 hours of our combined 1,200 hours in our EZs and it seems to me that we talk less now in the air and on the ground because we have shared something that we don't have to talk about. When we flew over the Canadian Rockies from Victoria to Calgary together we sure felt good. We met a lot of great people and we got tired. We didn't notice that we were changing even though we were probably different from other people to start with having chosen to build this unusual plane we were changing more. The people most deeply involved with the EZ have changed even more. Burt is warmer and friendlier, Dick is happier, and I don't think that success alone can

account for all of this. The plane and the people play a very important

---

part in what has happened to all or us. Bernadette and I fell in love with each other and the airplane all at the same time and it has only gotten better. If we are unable to fly "Puff" for a week or two or a month or two as when we changed engines; a part of us doesn't feel right. We fly another plane but that isn't what we need. We flew "Puff" over 280 hours that first year 1978 and spent more money than we earned but it was fantastic. We were the first EZ into a lot of airports. But we now know that it wasn't the novelty of the travel itself. It was the airplane and the intimacy of the three of us. We fly around the valley now, above the smog in the late evening, put "Puff" in the hangar and still shake our heads in the awe and wonder of what we have experienced together. For ten wild weeks in the fall of 1979 we commuted between La Verne (near Los Angeles) and Reno, Nevada, sometimes up the Owens Valley (that can be a very nasty valley, we ran into snowstorms, had to stay at Mammoth one night til the storm broke) and sometimes we would fly the west side of the Sierras and then across the Sierras by Donner Pass. Those were always 3 to 3 1/2 hour flights, fast, using nearly all of our limited fuel capacity at 10 to 12 thousand feet. Even with electric socks my feet would be nearly frozen. November and December were bad, but there was never any question in our minds, there was no other way to make a trip except in "Puff". Once the weather was so bad we had to fly commercial. We were uncomfortable in the seat. The pilot handled the plane roughly and we had to sit and wait a lot. And we missed "Puff". We've owned other airplanes and they aren't the same and they don't do the same things to you. We've talked a lot to pilots of other planes. They don't seem to know much about airplanes. They fly but they don't seem to live it. They don't seem to have the zest for flying, or the need, maybe that's really it. We have to do it. The other EZ people seem to be the same.

VariEze Weights.

Bill and Lynn Butters recently completed their VariEze, N235LB, and it is a beauty. They kept very accurate track of the weights throughout the building process. Their airplane is an excellent example, weight-wise. With an O-235 Lycoming engine, and light weight alternator, the airplane weighs 634 lbs empty.

Here is a summary of weights that Bill sent in to us. We are publishing it so that it may be used as a guideline for VariEze builders, much the same as the weight information from Mike and Sally's Long-EZ, which was published in CP26 and CP27.

Item	Bare Glass	F.Filled & Sanded	Finished
Rt wing	34(no winglet)	40.9	41.5
Lt wing	34 " "	40.8	41.5
R Aileron		4.2	4.5
L Aileron		4.2	4.5
Canard	17.4		19.8

Canopy			13.2
Spar	21.2		
Cowl	22.0		25.2
Fuselage	174		
on gear			

Engine with mags (O-235)		196
Prop ext. & bolts		5.5
Prop (Hegy)		8.25
Crush Plate & bolts		2.5
Carb		3.5
Spinner		5.0
Exhaust		4.0
Baffles		4.5
Alternator		4.8
Mag Leads		8.5
Engine mount & hardware		6.5
Radios		7.8
Seat belts		10.0
Instruments		12.0
Upholstery		11.5
		624.0
	Phantom Weight	10.0
		634.0

Question: Can I use a constant speed or variable speed prop on my VariEze or Long-EZ?

Answer: We do not recommend the use of this type prop, for several reasons. (1) weight on the tail (2) complexity and (3) the prop on a pusher like an Eze, gets a fore/aft bending load on each blade, twice per revolution as the propeller passes through the wake of the wing/centersection. This input can resonate and fail a metal prop or metal hub assembly. Only the solid wood prop is known to have an adequate safety history for this application. An "experimental" variable pitch prop recently destroyed the Q2 prototype. Also, as the following letter indicates, many or most prop developers experience failures which can prove fatal:

Gentlemen,

Rudi Kurth of Busswil, Switzerland who has a VariEze, has been working on an electrically actuated variable propeller. When completed he tried it in the Eze as a ground test stand. The propeller came apart within a few moments and ripped the engine out of the mounts doing considerable damage to the aircraft.

Whether this was due to poor design of the hub or the whirl mode I am not sure, but the propeller busted and that, for whatever reason, is vindication of the facts you presented to me. Again, thank you.

Sincerely,
James B. Fleming

Builder Hints
Long-EZ
Ref: Section I Page 9-2 and 9-3
Attaching axles to the main gear strut: CAUTION! You must set the toe-in parallel to the WL, not 90 degrees to the strut as several

builders have tried to do. The main gear strut should be mounted on the fuselage. A good idea at this point, is to stretch a tight wire down the fuselage centerline, at the level of the axle centers. This assumes your fuselage is upside down, with the main gear strut sticking up. Using a rasp or a course file, trim the faces of the strut where the axles will be mounted, to roughly give you the correct toe in. Try the brake plates on, to be sure that they seat flat onto the axle flanges. You may have to file a small radius into the brake plate to get it to seat properly. Now, position the axles on the gear, the flat machined areas on the axle flanges should be oriented close to vertical, and the bottom of the flanges should be approximately 1/2 inch up from the bottom of the gear strut. The brake caliper must be oriented forward and the top (with the airplane upright) of the caliper will be level with the top longerons or W.L. With these parameters, there is only one way that you can install the axle/brake plate/caliper assembly. When you cut the main gear strut to clear the caliper, be absolutely certain that there is a minimum of 1/16" between the caliper and the strut. The caliper must not be able to touch the strut at all, or you can have an intermittent or failed brake. Now, layup 3 plies of BID both sides of each strut and mount the axles using clamps to position the axles such that you can place a 24 inch steel carpenters square on the axles as shown on page 9-3 (section I). With the square held in position on the axle, measure from the forward tip of the square to the tight wire, (1/2 of dim. A) and from the heel of the square to the tight wire (1/2 of dim. B). The difference between these dimensions, (1/2 dim. B) minus (1/2 dim. A) should be a minimum of 0.1" to a maximum of 0.2". The smaller dimension is better, this is approximately 1/4 degree of toe-in, and will give excellent tire wear. N26MS was done this way and now has over 500 landings on the original set of tires.

Lone-EZ Ref: Section I, Chapter 6
When you assemble your fuselage sides to the bulkheads, be sure to install the firewall first, then the aft seat bulkhead, the forward seat bulkhead, the instrument panel, F22 bulkhead and then F28. If it is done in this order you will have little trouble bending the sides. There may be a tendency for the foam to crack in the area of the aft seat bulkhead. To avoid this possibility, particularly when working in a cool or cold shop, apply local heat with a hair dryer, to the foam. This will greatly reduce any possibility of cracking foam.

Long-EZ Elevator Templates
Ref: Section I Page 11-1, step I.
A few builders have reported that they have cut the templates accurately, and still ended up with oversize foam cores after hotwiring the elevators. It appears that perhaps we allowed a little too much allowance for the hot wire burn-down. So when you make your elevator templates, go ahead and clamp them together, and sand down not just to the line, but you should sand virtually all of the line off. Check your templates carefully against the full size drawing on page 11-5. Remember that 2 plies of UND (the skin) will add only .018" to the size of the foam core. Be absolutely certain your foam cores are perfect before you glass the skins.

Long-EZ Pitot Tube
Ref: Section I page 13-10, step 6.
Install the pitot tube so that it runs uphill continuously from the tip of the nose to the airspeed indicator. The easiest way is to run it aft through NG31, then over against the left side, and all the way uphill to the airspeed indicator. The tube can be attached to the fuselage side with a few narrow strips of BID.

Homebuilt Fuel/Baggage Strakes
Ref: Section I page 21-7.
Builders have reported that they built the fuel strakes without installing the wings, and when they came to installing the foam block between the wing root and the diagonal rib (O.D.) the top of the strake was too high to fair in nicely with the wing. When you are ready to install the top cover on the fuel strakes, install the wing, and check with a straight edge that you will have a nice fit to the wing. If necessary, trim the O.D. rib down before installing the tank top.

Hotwire Templates
When making identical templates, (canard, elevators, etc.) clamp them together, and use your Disston abrader to sand them to exactly the same shape. This is also valid for canard jigs.

Hotwire Cutting The Canard
Ref: Section I page 10-1, step 1.
An excellent suggestion for hotwire cutting the four foam cores for the canard is to use the outboard templates (no spar trough) only, to cut all four cores. Then use the inboard templates to cut the spar troughs on the two inboard cores. Caution: If you use this method you must leave the cores in the blocks weighted onto your table during the trough cuts. Otherwise, if the cores warp, the trough depth will vary incorrectly along the span.

This method makes certain that all four cores are identical, and also lets you cut well defined spar troughs, with no lag in the corners.

Epoxy Balance
Paul Burch had improved his balance by glueing a Sears line and surface utility level (around $3.00) to the beam. This allows you to see when you are getting close with the hardener, and also makes certain that the whole balance is level. Parallax errors are also eliminated.

Worm/Wormgear Retract Mechanism
Some builders have experienced "chatter" when extending the nose gear while static on the ground. While this has never been a problem in the air, due to air loads, it is possible to minimize this by checking alignment of worm and wormgear, and also backlash between worm and wormgear. If you have fore-aft movement of the worm, use a washer to shim it snug. This will eliminate the chatter.

Wiring From The Wing To The Centersection
Cut a 2" diameter hole in the outboard bulkheads in the centersection spar, opposite the point where the wiring comes inboard through the hotwired holes in the wing cores. Mike bought some pin male and female plugs and sockets from Radio Shack and wired nav. lights and strobe lights through these plugs and sockets, breaking the wiring bundle a few inches inside the centersection spar. This enables you to reach in

through the hole in the bottom of the centersection spar, and pull the wiring bundle down and out so that it may be disconnected in order to remove a wing. The comm. antenna (s) should of course also have a BNC connector at the same location. Mike ran his Nav/Strobe light wiring bundle out through the wing, together with the comm. antenna coax and has no perceptible interference. All this wiring is now brought inboard through a hole cut in the CS6 and CS7 bulkheads (a 1" diameter hole is fine) and then inboard to just inside the fuselage sides at which point you can drill up to a 1/2" diameter hole in the forward bottom of the spar box, and run the wiring down through these holes into the area aft of the back seat bulkhead.
CAUTION! Do not drill through the lower spar cap.

Transponder Antenna
The transponder antenna can be mounted under the front seat thigh support, and this is where quite a lot of builders have located it, however, Jim Weir of Radio Systems Technology has cautioned that it may be possible that high powered microwave energy may be radiating in very close proximity to a rather sensitive part of the pilots anatomy. To put it bluntly, it may be a little like sticking your fanny into a microwave oven! In any event, no qualified person to our knowledge has tested this, so it may be prudent to laminate a sheet of aluminum foil under the thigh support. Microwave energy will not penetrate the thinnest of metallic foils.

Wicks Aircraft
Now have brushable "Spray-Latt" canopy protective material in stock. They also carry the full line of VDO instruments and still have the Whelen strobe/nav light system (single flash) for Long-EZs.

Prefab 500 x 5 wheel pants, are now available from Aircraft Spruce and Wicks Aircraft. Hardware kits to install these wheel pants are also in stock. Instructions for installation of the 500 x 5 wheel pants are essentially the same as for the 3.40 x 5 wheel pants, except that 16 K1000-3 nut plates should be installed evenly spaced on the flange, instead of 11. .062 thick 2024-T3 aluminum is substituted for .032 for the mounting bracket. See CP 28, page 10 for these instructions.

Long-EZ and VariEze "Throw Over" Stay
Many builders noticed these neat canopy stays on Burt's, Mike's and Dick's Long-EZs at Oshkosh, and requested information on how to build one. The original idea for this came from Bob Woodall who has one on his VariEze. He had his on at Oshkosh 1980. The stay is constructed from aluminum tubing (2024-T3) .035 wall x 3/8" O.D. and a few small pieces of .025 thick 2024-T3 aluminum flat stock.. The small bushings shown were obtained from a surplus supply house in Los Angeles several years ago and we are not aware of a good source for these. The pivoting stay is mounted to the top of the roll over structure, we simply drilled a 3/4" diameter hole in the back of the roll over structure, and pushed a 3/4" wood dowel into the roll over, floxed it into place and layed up a ply of BID over it, inside the roll over to retain it. The other end is mounted to an additional hard point in the canopy frame, which is exactly the same as the rest of the hard points called out for, for hinges and canopy latches. This is not difficult to do even if your airplane is complete. Drawing next page.

Canopy Stay **DRAWINGS OMITTED**

PLANS CHANGES
We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LONG-EZ PLANS CHANGES

LPC #75 Section I, page 9-1
The axle bolt location in the sketch on the lower left is not accurate. See sketch below. Warning - Note that the 1/16" clearance between the main gear strut and the brake caliper is a mandatory requirement. The caliper must not be able to touch the strut or the wheel pant or you could have an intermittent brake or even a brake failure. **SKETCH OMITTED**

LPC #76 Section I, page 11-5
"See detail page 5.4" should read "see detail page 11-4".

LPC #77 Section I, page 19-18. Step 11.
"Refer to chapter 6 and 7" should be "refer to pages 14-8 and 14-9".

LPC #78 Section I, page. Antennas.
Nav. antenna DES should be cut into two equal lengths from a 48" piece. Change the length to 22.8" long, not 24".

LPC #79 Section I, page 2-4. Chapter 13 material list.
SC fiberglass strut cover is listed twice.

LPC #80 'A' drawings, page A-5.
2" x 2" x 1/4" aluminum ext. shown full size page 18-3, should be page 9-3.

LPC #81 Section I, page 19-14. Section E-E.
Detail A shows the rodend bolt on the CS 132L belhorn reversed. Anytime a rodend is cantilevered off one side of a belhorn, the bolt head must be on the belhorn side, see sketches below:
SKETCHES OMITTED

LPC #82 Section I, page 5-2, step 2.
One ply of BID extend entire 103" length, this ply of BID should be at 45 degree and can be in several pieces.

LPC #83 Section I, page 9-4.
The AN960-1018 washers called out should be AN960-1016 and are not called out in the bill of materials on page 2-4. Add 4 more AN960-1016 to the 2 washers called out.

LPC #84 MEO Section I, page 21-5, step 10.
We omitted to tell you to micro a urethane foam block (2 lbs.ft3 green) to the 'flat' leading edges of the strakes, see page 21-7, cure, then carve to match proper leading edge contour (ribs R23, R45 and the wing). Slurry the foam and lay up two plies of UND crossing each other at 45 degrees to the leading edge of the strakes. Lap this layup 1/2" onto the strakes top and bottom.

LPC #85 MEO 'A' drawings, page A5, to right.
"shown full size, page 18.3" should be "page 9-3".

LPC #86 MAN/10HRS Rudder pedal weldments.
Before 10 hours of flight the top tab welded to the rudder pedal (see section I, page 13-3) must be reinforced per Figure 2, page 5 this newsletter. Also change the full size drawings on page 13-3 to show the top tab per Figure 1, page 5 this CP.

LPC #87 Chapter 13, page 4.
Change wall thickness on NG17 to .188. Change wire diameter of spring to .083.

VARIEZE PLANS CHANGES

MEO, Canard Pusher #23, page 8.
VDO 240-023 sender is not correct. The correct part number is VDO-360-25.

MAN,
See LPC #75 on note concerning clearance required on caliper to strut.

ACCIDENTS/INCIDENTS

Take Off Incident
Byron McKean damaged his VariEze in an aborted takeoff. He took time off from the repair job to write the following story for us in the hopes that publishing this information may prevent someone else from having the same problems:
"The takeoff direction was to the SE with a mild left cross wind. The runway is 2,650 ft. long, very narrow, and very bumpy and rough. There is considerable grass that is six to eight inches high growing onto the edges of the runway. There had been considerable rain in the early hours of the morning and there were numerous puddles of water on the runway. My takeoff attempt was intended to miss the majority of the puddles but my right wheel hit a long puddle causing the aircraft to veer about ten degrees to the right. I was near take off speed and saw the grass on the runway ahead of me so I attempted to lift off unsuccessfully. Seeing that flight was impossible I reduced the power, the nose dropped sharply breaking off the nose wheel followed by the nose strut collapsing into the retracted position. Additional resistance of the grass on the right side caused the aircraft to veer off the runway and into the muddy plowed field where the main gear collapsed and we all came to a stop. From the spot of the main gear collapsing to the stopped position was around fifty feet. I turned the switches off then got out and assisted my passenger out. There were no injuries other than my passenger having sore knees from pressure against the back of the front seat. We both wore seat belts and a two strap shoulder harness. The ELT did activate.

Later, upon investigation, I found a small piece of broken fiberglass wedged between the right brake puck and the brake disk. I was unable to rotate the wheel. Since the right wheel pant was torn off the landing gear prior to the main gear collapsing I now wonder if this could have caused more drag on the right side far greater than what the grass caused. Without this additional drag a "save" may have been possible.

I can understand now that when I hit the water and was pulled slightly to the right the wheel entered increasingly deeper water causing more drag and more turning to the right. There is that moment of delay while the mind digests what is happening until a response is initiated. That moment is too long.

It is interesting to me what thoughts go through the mind during the short interval of an emergency.

Some of my thoughts...
Look at all those puddles of water. Better choose a good path and try to miss most of them.. Narrow runway, run the engine up full before releasing the brakes. 2,500 rpm ok, oil pressure up, let's go. Boy is this a rough runway, nose bouncing, come on airspeed let's get the nose off this rough stuff. Ah here comes some airspeed, nose slightly off, not too much. Now here comes that long puddle, left cross wind, going to hit the water a little bit with the right wheel.. Airspeed approaching lift off, my God that water is pulling me right, this isn't

supposed to happen, come on airspeed, here comes that grass, can't hit that, can't fly if I hit that, try for a lift off, nose up... up... nose is plenty high, if it does lift off can I fly out of ground effect, don't want to end up in the bay at the end of the runway, what if the wing drops and hits the ground, no good, won't fly, damn, hit the grass, noisy, lots of drag, being pulled to the right, this can't happen... chop the power, keep wings level, bang! my gosh, I broke something, this is a crash, What an experience for my passenger, first time in a homebuilt and doesn't particularly like flying... sick... sick... sick... there goes the main gear, here comes the field, turning right, keep it level, keep eyes open, keep thinking, look... I'm still ok, hang on, brace, keep looking, it's stopped, I've really messed it up. Switches off, get out now, what about a fire, get my passenger out. We are both ok but look at my pride and joy, belly in the mud, mud everywhere, look back at where I've been!

CP30, Page 9

My VariEze is equipped with a Compucruise computer that includes a fuel flow sensor. In order to use a fuel flow sensor on a VariEze you must install an electric fuel pump. I also installed a four-way fuel selector valve so that I could select a "by-pass" position in the event of a malfunction of the electric pump, flow sensor, or inline fuel filter.

I mounted the electric fuel pump and fuel flow sensor on the center section of the main landing gear behind the rear seat. I now recognize that this is a no no! When the main landing gear collapsed it tore the fuel lines loose. Had the fuel flow sensor and electric pump been attached to the fuselage or firewall no leak would have occurred. Even the gascolator that extends slightly below the firewall into the air intake scoop was undamaged".

Forced Landings
The following information was supplied by Bruce Muirhead, from Colorado:

"Dear Burt,
I guess I should report a couple forced landings we experienced.

The first was on an early frosty morning flight from Pagosa, NE, over the Rockies to Boulder. I may tell the whole story in more detail another time but suffice to say here that it was a variation of the old "gas cap" story. The right cap didn't get secured, fell off on take off (damaging the prop some), but I didn't catch on until a temporary power loss got me to thinking over the Sangre de Christos. As Mary continued to report plenty of gas in the right tank but left running low, I was guided to make a sharp right turn and head for the plains.

There we spotted the Air Force Academy chapel and turned north, still at 12,000. A minute or two later, flame-out. We did a 180 and glided 20 miles, straight into the Academy's north-south runway, unannounced, uneventful and followed by lots of red tape.

The second was on the way to Taos for the IVHC fly-in just 35 minutes from here. Just over the mountains and letting down 25 miles from Taos

it quit. Fuel starvation on descent? Nose up - no luck. No reserve - faulty valve. A straight section of highway complete with a convenient turnoff made for another uneventful landing - at the New Mexico Port of Entry! Borrowed the officer's pickup, got five of regular, prop, run up ok, and took off on our "runway" for Taos. There most of the 19 VE pilots discussed my problem and the consensus was clogged vent line. That's what it was, thought what I dug out of it was hardly enough to analyze. Even the little fuselage tank vent was plugged. Anyhow, you can bet those other 18 pilots at Taos will check their vent lines, and probably also,
Yours truly,
Bruce Muirhead.

RAF comment - we don't know why Bruce was unable to use the reserve tank to save the situation for both these cases - apparently the "faulty valve". You VariEze guys should always keep your reserve system in good operating order - its your redundancy to protect against vent clog, lost cap etc. Note: The Long-EZ while not having the reserve tank, has separate left and right pumped systems (which feed with a lost cap) and separate vents.

Engine Failure, On Top, Over Lake Michigan
A VariEze accident claimed the lives of a New York couple and their son enroute home from Oshkosh. The pilot was a low-time relatively new private pilot taking his first cross-country trip in the airplane, which had 49 hours total time. The following information is from a VariEze pilot who was flying with the Eze that crashed, and from FAA investigators.

The flight was heading east across Lake Michigan to save trip length even though it was over a solid under cast with tops at 10,000 feet. They were cruising at 11,500 feet directly over the center of the lake when the pilot noticed zero oil pressure. They continued another 10 to 15 miles when the engine lost power, then quit. The wingman noted that the pilot kept turning right during the trip and he had to keep instructing him to turn left to remain on course. He repeated this instruction as the pilot descended into the clouds in a right turn. Radio communication was lost when he tried to get him to switch to Muskegon Tower frequency for vectoring. Weather at the surface was a variable ceiling ranging from 500 scattered to 1,500 broken to 4,000 overcast.

It is not known whether the pilot became disoriented in clouds during the descent. The last call heard by the wingman was a very upset voice repeating 'engine quit, going down'. Flight service received a call of 'shoreline in sight' with no further communication. The aircraft crashed while in a turn in a down-wind direction at the far end of a 150 foot long clearing, immediately cartwheeling into trees. There was no way to survive a landing where the aircraft impacted. There was no fire. It is not known why the pilot selected the small clearing when the shoreline with alignment into the wind was apparently available to him.

Investigators determined the cause of engine failure to be oil loss through a broken oil pressure sender line. The line was aluminum tubing, flared with an incorrect automotive flaring tool. It fractured at the fitting sleeve where it had been previously bent 45 degrees.

The purpose of us printing details of this kind of tragedy in this newsletter is to alert those flying other airplanes to conditions that might cause another accident so that recurrence can be prevented. If you are flying an airplane that may have an engine installation that has not been inspected by a qualified A.I., ground it until it is adequately inspected for aircraft-approved installation materials and workmanship. All plumbing of oil and fuel lines must be of components approved for a certified installation. If you have aluminum tubing installed, replace it with approved flex hose before flight.

Canopy Emergency
Joan Richey, Los Cruces, NM experienced a canopy emergency in her VariEze. As is generally the case, she forgot to lock it due to an unusual break in routine. Her full story follows:
"Charles, and my instructor, Joe Gold, had started the Eze and said he'd like to fly it a little, too. So I took off, flew over town and up the valley some, came back, landed, taxied up to where Joe was waiting, got out, he got in (engine still running), a friend came up and asked for a ride. Joe shot a landing, came back, jumped out, ran around the plane sniffing - smelled something burning. Took up the passenger, came back, changed passengers, said the radio had burned up. Took off, flew a short time, came back and I decided to fly again. "Ok" says he "but don't even fool with the radio

---

because it's not working". Didn't turn off the engine. I climbed in, said I'd shoot 3 landings and take it to the hangar. I always fly with earplugs under the head-set - didn't take time to put them in. That's #1. Engine hadn't been stopped - didn't do my standard check with run up. That's #2. Took off and did not bring up the gear since I was just going to shoot landings. On turning downwind to base, the sound in the cockpit changed but I could not identify it (no earplugs). Base to final, the canopy popped up to the full throw of the safety latch. I panicked! All the stories Charles had told me and I had read of canopies coming open, all of a sudden, seemed to have culminated in funerals. My initial thought was "I'm dead". Tried to hold the safety latch down, tried to latch the canopy. After the initial panic, I remembered some words of wisdom in a CP Charles and I had discussed. FLY THE AIRPLANE! Next thought - "Climb, gain altitude and latch the canopy". Third thought - "Land it!" By now, the panic is gone, I'm a little high and a little fast. Have not managed to trim it to landing speed. After all, a girl's only got two hands and both are holding down the canopy! Actually, I manhandled it down, long and hot luckily 12/30 at Las Cruces is 7,500 feet. Let it roll to a stop and then drove it to the departure end of the runway. (Furthest from buildings and people). Stopped - knees weak could not latch the canopy. Opened it completely, latched it. TURNED ON THE MASTER - CHECKED THE SAFETY LIGHT AND BUZZER - turned around and took off on 12. Shot two more landings, took it to Las Cruces Aviation, met on the ramp by Joe Gold, illustrious flight instructor, and my brother who was about to go up in his Citabria. NO ONE EVEN NOTICED! but to me it was scary".

Shopping

New Long-EZ prefab parts available now from Task:
Long-EZ fuel/baggage/strake kit, includes ribs and baffles - 16 pieces. The kit is also available without ribs and baffles.

1 NG-31 Foam cut to plan and glassed both sides.
2 NG-30 Both laid up per drawings - predrilled 5 places.
1 F6 with overlaps formed as done on page 13-6
1 F22 per drawings including doubler and extra plies.
1 F28 Notched for assembly.
1 Instrument Panel, notched and drilled - except instrument and radio holes.
1 Front seat back - with notches and cut outs.
1 Rear seat back - with notches and cut outs.
1 FSRC formed 90 degree - trim and install (console)
1 RSRC formed 90 degree
1 FSLC - including 9.1" x 8" separate pc. per page 24-1.
1 RSCL formed 90 degree - Trim and install
1 Front thigh support, formed and glassed, 2 ribs included.
1 Rollover structure, formed, glassed rear closure insert included.
All of the above parts are vacuum bagged, prepreg, which results in lightweight, excellent-quality parts. We have a display of these parts at RAF. Anyone who may have purchased prefab strakes from Task, and do not have installation instructions, write to Task. For more information, send a SASE to:

Task Research,
848 East Santa Maria St,
Santa Paula, CA 93060
(805) 525-4445

We have had two of B & C Specialty's excellent little alternators on test for over a year now. The belt driven type for Lycomings has been running on the prototype Long-EZ N79RA for over 340 hours, and has been trouble free. The Continental, gear driven alternator has not missed a beat in the prototype VariEze, N4EZ for over 100 hours. Many of the alternators are installed in homebuilt VariEzes and Long-EZs, and we are not aware of any failures. Bill is to be commended for his excellent solution to our need for lightweight electrical power. Send Bill a SASE for a brochure with color photos.

Performance Flight Testing Lecture

This year at Oshkosh, Burt presented a lecture on basic methods to conduct performance flight tests and on data corrections and standardization methods. Many in the audience asked for a list of the equations used, so he promised to print them in CP #30. Room here does not allow a presentation of the total lecture with pilot techniques, but those who were in attendance will be able to use the information below: **EQUATIONS OMITTED**

The RAF Model 68 Amsoil Racer
In late 1979 Burt designed an aircraft for Dan Mortensen to fit the specifications for racing biplanes. In 1980 Dan received sponsorship from Amsoil to build and race a prototype. The aircraft (N3OILS), built by a team in Sacramento, California, was completed in August '81. It was entered in the 1981 Reno Air Races in September. Although it turned several record-exceeding laps during a heat race, it finished only third in the final race due to several pylon cuts. The pylon cuts were the result of a roll deficiency in the control system.

Dan delivered N3OILS to RAF in October so we could evaluate it and help him complete its development. Except for the roll deficiency, which was caused by inadequate travel and stiffness of the controls, the Racer has proven to be an excellent flying aircraft with good firm flying qualities at its 240 mph racing speed. It's takeoff and landing distances and handling are good. Dan plans to make some improvements in it's engine installation and propeller which should assure its racing success in the next season.

The Model 68 is very similar to the RAF Model 54 Quickie, using the reversed stagger tandem wing concept with wheels at canard tips. It uses some previously unflown airfoils, which have been now shown by test to be delivering over 60% chord natural laminar flow. The NLF is attained even within the prop wash!

Of particular note is the use of the small horizontal "T" tail. The tail is an all flying type and is geared to operate with the canard elevator control system. Note that this is the first use of a Horizontal tail on Rutan designed aircraft. Its purpose is to force the forward elevator to the proper positions to optimize canard airfoil camber for both the 250 mph straight aways and the 4g turns. Also, the horizontal tail fine tunes the aeroelastic effects to increase pitch stability at very high speeds. Despite the use of carbon fiber in it's construction, the Model 68 is a relatively flexible airframe for a 250 mph application. The design parameters for the tail were verified by the flight tests.

VARIVIGGEN NEWS by Mike Melvill

Oshkosh was 'big' this year. More people and planes than ever. But this year was special. There has been a VariViggen at Oshkosh for 10 years straight. The first six years were Burt's N27VV, the original prototype, now in the EAA museum, and then my Viggen N27MS, made its Oshkosh debut the following year and has been at the airshow for four straight years. 1981 was the first time more than one VariViggen was present. Ken Winter of Tulsa, Oklahoma, flew his very excellent Viggen

in and I had the pleasure of flying in formation with Ken in the fly bys. Ken also was kind enough to give rides to a lot of Viggen builders during the week. Hopefully, this will give those builders a shot in the arm so to speak, and they should have gone home and really gotten busy on their Viggen projects.

I flew my Viggen out to Oshkosh and back. Our route took us Mojave to St. George, Utah, to Aspen, Colorado. Spent the night there and departed the next morning with a density altitude of 10,800 feet, climbed over the Divide west of Boulder, Colorado and flew to Hastings, Nebraska. From Hastings to Bascobel, Wisconsin and to Oshkosh. After Oshkosh we took the long route home via Anderson, Indiana, to Joplin, Missouri, to spend the night in Abilene, Texas. Next morning on to Alamagordo, New Mexico where we visited with our eldest son. From Alamagordo we flew via Albuquerque, Farmington, Monument Valley to Page, non stop. From Page we flew the Colorado river and over the Grand Canyon, then back home to Mojave. We covered 4600 miles and I put 35 hours on the tack. The Viggen required 2 quarts of oil, and that was all. My Mother was my back seat passenger, and she really enjoyed her trip in the Viggen. She says the Viggen is the greatest (but she may be biased!).

We almost had a third Viggen at Oshkosh. Arthur Schwartz started for Oshkosh and got as far as Youngstown Ohio, and was turned back by low visibility and rain. Arthur was keenly disappointed in not making it to Oshkosh, but reports that he has 116 hours on his airplane. He has flown in and out of all kinds of airports in various weather conditions, including 90 degree crosswind of 20 knots, without difficulty.

He reports another bonus of being a Viggen flyer - when you land, the crowds gather, people take pictures, and even want your autograph!, so he says to all VariViggen builders who have been taking it easy, and not working on their birds to "get busy and sample the pleasure and ecstasy with the feeling of having something unique, matchless and most beautiful".

Leonard Dobson made his first flight in his Viggen, shown in CP29, on August 1st, 1981. He was not able to make it to Oshkosh, but he is having a great time flying his time off. His letter is printed below.

Terry Galbreath reports that he is making good progress and expects to have his Viggen on the gear by Christmas. Terry had been to Washington Hardware and got about 30% of his bolts there and says that you should take a bolt gauge with you.

Frank Stites sent a photo of his Viggen, and it requires only wing fuel tanks and canopies and it is ready. It looks excellent. Frank has the composite special wing. Arthur Schwartz flew up to visit Frank a week or two ago, so that should motivate Frank to get her in the air!

Keith Armstrong has requested that we have a VariViggen bull session at Oshkosh next year. I agree, Keith, and we will set something up. This year the builders organized something themselves, but unfortunately I was so busy with other RAF duties, I was unable to be there. Keith reports that he used "constant force" springs for the helper springs in his main gear. These are similar to what I used, and mine have worked

perfectly. The biggest drawback to this type of spring is the price. You can obtain more information from:

John Evans Sons Inc.,
Springs Ave.,
Lansdale, Pa 19446
(215)368-7700

Keith used part #R433W and found that two per side were required.

The following is "Dobby" Dobson's report:
FIRST FLIGHT: The event was purposely kept low key, with no advance publicity on date or time. I had two fellow EAA members who were familiar with the Viggen to assist me. They each inspected the aircraft, and checked my weight and balance figures. They also made sure that I used my check list for pre-flight before they turned me loose, and got in the chase plane. At approximately 9:00 am, August 1st, '81 three years and one month after the start of construction, Rutan VariViggen N73LD serial #533 lifted off at Georgetown, Texas airport. Some preliminary "pilot induced oscillation" and wing rock caused by nervousness and heavy handed input made the take-off a little wild. However, I established a rate of climb at about 800 ft per minute, levelled off at 3000 feet and then took a few seconds off to congratulate myself on my achievement so far. I did not retract the gear during this flight, and kept the speed below 120 mph. I spent the next thirty minutes getting acquainted with the airplane, and then made two simulated approaches and landings at altitude. Cylinder head temperature had been running on the high side to I decided to terminate the flight before I had completed my program. The landing was interesting. It is very difficult to break the habit of years of making stall landings. 2000 or so hours in Cessnas, Pipers, and Beeches doesn't make one an expert in a Viggen! Finding the correct pitch attitude is the tough part. I have an angle of attack indicator, but by the time I get it calibrated, I probably won't need it any more.

Second Flight: Was much more enjoyable because I was relaxed. Take-off and landing were beautiful. Handling in the air was delightful. My wife was a passenger in the chase plane, and she described the flight as that of a graceful yellow butterfly. Gear retraction and extension worked perfectly, and engine cooling was much better. (I had improved baffling). After 20 hours of flying time I have some observations, impressions, and advice for what it may be worth to some of you Viggen builders.

1. High speed taxi test and lift-offs: I found that a 4000 ft runway was not long enough for me. On my last run, I had to use a rough over-run to stop, and it was a helluva way to test the gear!
2. Brakes: Go back and read Mike's article on brake and master cylinder compatibility in CP #23 Page 9, I made the same mistake Mike did, and I should have made the correction when I first read about the problem instead of verifying it in my own aircraft.
3. Preparation for First Flight: Make every effort to get some time in a light weight homebuilt that has extremely sensitive controls. If you can fly a canard pusher, so much the better. If you can fly in the front seat, you have it made. Sit in the front cockpit of your Viggen with the fuselage propped up to about a six or seven degree angle, and pick out something in the cockpit, or put a mark on the canopy, so that you have a ready reference for that pitch angle.
4. Squawk Sheet: Correct any problems after each flight, or before flying again. Don't let them pile up. Nobody says you have to fly the

restrictions off in a week or a month. Use the time to "fine tune" your airplane.
5. Program your test flights. My Viggen costs me about $18 per hour to fly just for fuel. That amounts to $720 to fly off the restrictions. I intend for it to be a worthwhile expenditure, by making up my own flight manual on performance and flying characteristics, instead of just aimlessly flying around in circles.
6. Handling: I have heard and read many stories of homebuilders praising the ability of their creations to fly "hands off". My Viggen is not a "hands off" airplane. I neither wanted it to be or expected it to be in that category. Either I fly it or it will fly me, but I love it. I tweak the stick in any direction and it responds! It goes fast and it goes slow. I am constantly amazed at the abrupt, sharp turn capabilities. The first time I felt the tiny little nibble of the canard as it stalled, I laughed out loud like a kit with a new toy.
7. Viggen Production: Plans for the VariViggen have been available since 1974, but very few airplanes have been completed and flown, and that is too bad. Sure it's a complex airplane to build and sure it's not cheap, but it has sure been a worthwhile project. My Viggen is not a Grand Champion or even close to it, but

---

it sure draws a crowd. Hundreds of people have admired it both in the air and on the ground. I have approximately 50 requests for rides when the restrictions are flown off. Included in this group are a number of corporate pilots who fly Gulfstreams, Lears, MU-2s, King Airs and 421s. These are pilots who have to wear neckties when they fly, and generally don't get overly enthusiastic about any airplane.

I can only hope that this report from an enthusiastic youngster of 68, will get some of you guys back on the stick and finish your Viggens.

Statistics of N73LD:

Engine:	Lycoming O-360 A1D 180 HP
Prop	Hendrickson 70 x 70 Wood
Empty Wt:	1236 lbs.
Gross Wt:	1860 lbs.
Fuel:	Main Tank 30 gals. Wing - 6 gal each
Range:	650/700 miles
Wing:	Standard, composite construction with full span ailerons.

Thank you Mike and Sally for all your help, and also thanks to Burt for a good design and support during construction.
A special thanks to Jim Cavis of Scottsdale for getting me started on the Viggen project. Please, Jim, finish your airplane - you will love it.

Yours sincerely,
Leonard "Dobby" Dobson.

For Sale.
Lycoming O-360 180 hp. Zero since chrome major. New alternator, reconditioned magnetos. Can be either carburetor or fuel injection.

This highlighted photo shows the extent of laminar flow on the Model 68 Amsoil Racer. Note the loss of laminar flow caused by the strut transition and by several specks and insect strikes that cause a turbulent wedge of 15-degree angle.

The Model 73 scaled-demonstrator of Fairchild's Next Generation Trainer proposal. Note its small size. At 842 lb. empty, and 21.8-ft span it is probably the worlds smallest twin engine jet.

A portion of the grounds at Oshkosh. Guess where the Long-EZ forum is being held!!

NASA's Phil Brown and Bruce Holmes documenting the patterns of boundary layer transition on the canard of the Amsoil Racer. Note the small horizontal "T" tail.

Mike Melvill is at the controls of the "RAF jet" here on its third test flight. The complete, instrumented engineering flight test program (except spins) was completed at RAF in an incredibly fast 15-day time period. The all-composite, moldless-construction prototype flight demonstrator concept is proving to be a valuable, economical engineering tool for aircraft development.

Three Long-EZs in the flyby pattern at Oshkosh.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Jim Carlin and co-pilot (Lakeworth, FL.) getting some early stick time in their Long. Jim's workmanship is superb.

George Gilmer with his EZ, based at Santa Paula, CA. George is 74 and has been flying since 1928! George built all the parts of this EZ, including wheels and brakes.

The mostly-alert group of EZ builders, watching the construction video tape at Charlie and Betty Gray's meeting in Florida.

John Denver at Oshkosh shortly after his flight in the Long-EZ with Mike Melvill. His assessment of Mike's Long "farr-out!!" Photo by Bill Ebken.

Bob Woodall's EZ on display at the National Air and Space Museum, Washington, D.C.

Charlie Gray's Long fuselage in the assembly stage. Note the blocks on the flat table to hold the sides in symmetric alignment. Also note the mid-section bungee cord to hold things down and in for cure.

Brief Long-EZ specifications/Performance
Engine Lycoming 0-235 108 hp.

Span	26.3ft
Area	94.1 sq. ft.
Empty Basic	710 lb.
Empty Equipped	750 lb.
Solo Weight	960 lb
Gross Weight	1325 lb
Max Fuel	52 gal.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

Check items desired.	Price, includes first class mail	Overseas, Airmail - U.S. Funds only

U.S. & Canadian subscriptions	$6.75
Overseas (Airmail)	$8.75
Back Issues	$1.50

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 31. If you are building from 2nd Edition plans you must have newsletters 18 through 31. If you are building a VariEze from 1st Edition plans you must have newsletters from 10 to 31. If you are building a VariEze from 2nd Edition plans you must have newsletters from 16 through 31. If you are building a Long-EZ you must have newsletters from 24 through 31.

A current subscription for future issues is mandatory for builders, as this the only formal means to distribute mandatory changes.
Reproduction and redistribution of this newsletter is approved and encouraged. The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca. approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 on Saturday.
Closed Sunday.
If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to flyins. When arriving at Mojave by car turn east at the Carl's Jr. restaurant to find the airport.

When writing to RAF send a stamped, self addressed envelope along if you have any questions. If you are placing an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed up your reply.

Saturday Demos
Saturdays from 10:00 am to about 2:00 pm have been very busy with from 30 to 100 visitors showing up at the shop. Generally we have the VariViggen, the VariEze and two Long-EZs on display. We have been showing the construction video tape plus a very entertaining tape of RAF planes flying formation. We then generally have a "bull session" answering any builder or pilot questions and wind up with flying one or all of the airplanes, at around 1:00 pm.

RAF ACTIVITY
Since CP 30 has involved: Completion of our Model 73 jet flight test program, fabrication of our self-launching sailplane prototype,

completion and rollout of our new STOL research aircraft, hosting our annual workshop and providing homebuilder support.

RAF MODEL 77 SAILPLANE IS NAMED
Our entry in the SSA contest for a self-launching sailplane now has a name - SOLITAIRE. The Solitaire is a single-place sailplane with the intended capability to self launch, with a fixed engine and a retractable propeller. Its tandem-wing configuration allows the pilot to sit at the cg, eliminating the cg shift due to pilot weight that is common with standard sailplanes. The Solitaire has a 12.5 meter wingspan. If flight tests planned to begin next month are successful, the Solitaire will be offered for homebuilder construction. It will be marketed similarly to the Long-EZ, not as a complete kit. This results is considerable cost savings to the builder for materials. Also, the builder has the option of building or buying the prefab components. Further information on Solitaire will be released after it is flying, but in the mean time, please don't ask - we're very busy with the completion and test program.

For Sale At RAF
We do have the main and nose gears in stock. The main gear is shipped Greyhound bus, freight collect.

Main Gear	$309.00
Nose Gear	55.55

Canopies for pickup at RAF are taking about 2 to 3 weeks to arrive. We are not really keeping these in stock as we do have a storage problem. If you wish to pick up here at RAF, we will order for you and let you know when it comes in.

Bronze or Smoke	$249.00
Green	229.00
Clear	199.00

The new RAF patch (see photo) introduced at Oshkosh '81 is available from us. The large patch is $2.50 and the small patches are $1.50 each. The small patches are available for VariViggen, VariEze and Long-EZ.

The Long-EZ, VariEze and VariViggen silver belt buckles come in both mens and ladies sizes and also brushed finish or shiny. They are hand made in silver, from New Mexico. $25.00 each.

Video Tapes - Building the Rutan Composites.
This tape shows you the "how to" with composites. It is a great help for first timers as well as experienced builders. When ordering your tape, please specify whether it is VHS or Beta II. $59.95 plus $4.00 for postage.

Go-A-Long-EZ is a tape that covers the checkout, weight and balance of your aircraft, how to conduct the taxi tests and first flight.
$49.95 plus $4.00 for postage.

Orders for the Construction tape from overseas customers should be sent directly to the address below. Ferde will convert the VHS or BETA to the PAL system for you. At present he is only doing the construction tape.
Ferde Grofe Films,

702 Washington St.,
Suite 168,
Marina Del Rey, CA 90291

RAF BUILDER SUPPORT
It has become necessary to further clarify Rutan Aircraft's position in relation to the homebuilder and the support we give. Rutan Aircraft can only offer the assistance that helps them interpret the plans when they desire to build their aircraft like the prototype we have tested. We cannot assist in the design and construction of modifications. We cannot comment on the advisability of modifications. Many of the developments we design and test do not work as predicted. Thus, without testing your idea we cannot reliably predict its success. A similar situation exists for substitutions of materials. We will not be able to advise you on any material we have not tested ourselves.

LONG-EZ ACCEPTED
For amateur construction in Canada. Thanks to much hard work by the EAA Canada, in particular Edward Slack, the Long-EZ is now accepted by the Canadian DOT for amateur construction. Maximum take off weight allowed is 1325 lbs.

LONG-EZ FIRST FLIGHTS
The following is a list of all the Long-EZs flying that we know of. If you know of someone who has a Long-EZ flying, please send us his or her name, address, N-number and date of first flight.

Burt Rutan	CA	N79RA	June	1979
Johnny Murphy	FL	N21VE	June	1980
Mike Melvill	CA	N26MS	Dec	1980
Dick Rutan	CA	N169SH	Apr	1981
Richard Sparkman	FL	N506EZ	June	1981
Dan McElroy	WA	N80DZ	July	1981
Neil Hunter	FL	N141NH	Oct	1981
Ray Olsen	MN	N42DR	Oct	1981
Jerry Gruber	IN	N401EZ	Nov	1981
Harris Howard	TX	N25HC	Dec	1981
Robert Hansen	CA	N7LZ	Jan	1982
Joe Enrico	CA		Jan	1982

Many more Long-EZs are close to completion. By the time Oshkosh comes around, Long-EZs may even be close to VariEzes in number on the flight line!!

RAF MODEL 72, GRIZZLY ROLLOUT
The Rollout - On January 14th, 1982, at the Mojave California Airport, Rutan Aircraft Factory Inc. rolled out their latest prototype, the RAF Model 72 Grizzly. The new aircraft is a proof-of-concept prototype to be used to evaluate the feasibility of achieving STOL and amphibious capability with a canard/tandem-wing configuration.

Amphibious Floats - The aircraft will initially be tested in its bush configuration with four low-pressure tires on the main gear for soft or

unprepared fields. It will later be fitted with a new type of amphibious float system to allow it to operate from either water or hard-surfaced runways. The goal of the new float system is to allow operation from land to lake and back without the requirement to raise or lower wheels or to operate a water rudder. Schedule for testing the amphibious system will depend on the success of the flight test program with the bush configuration.

The Grizzly Details - The Grizzly is a four-place with a large baggage area. Power is the IO360-B, an injected 180 bhp 4 cylinder Lycoming. The prop is a constant-speed two-blade Hartzell. The sliding canopy has bulging side windows, allowing straight-down visibility for the pilots. Fuel is carried in the wing interconnects, keeping fuel away from the cabin while providing the torsional bracing required for the forward-swept wings. The four Fowler flaps average over 50 percent chord, adding over 45 square feet of wing area when deployed. The Grizzly airfoil and wing systems are the first to be developed by a new RAF aerodynamic design computer program which handles the complex interactions of tandem wings and high-lift devices. The structure is all composite, using fiberglass and carbon fiber facings/reinforcements with rigid foam sandwich cores. The Grizzly airframe is a test bed for evaluating and comparing several structural configurations. For example, the right wing is a hollow, sandwich-skin configuration and the left wing is the full-core construction technique pioneered on the VariEze. It's interesting to note that not only did the full core wing require far fewer man hours to build, it is also lighter and stiffer than the hollow wing. To enhance the go-anywhere, land-anywhere capability of the Grizzly, its cabin converts to sleep two, for camping. Folding the rear seat forward results in a level, 78 inch long bed.

The Grizzly Purpose - The Model 72 prototype is not intended for a specific market. RAF plans no certification/production of this model and it is considered too large for the homebuilt market. The purpose is research, to study canard aerodynamics in the STOL category. Our previous canard aircraft have not been designed for short-field operation. Thus, many have concluded that tandem-wing aircraft may not be suited for STOL performance. We do not have the definitive answers to this subject, but hope to gather the necessary data during the Model 72 test program to considerably expand our technology base. We expect the knowledge gained by testing this proof-of-concept aircraft will be invaluable for future developments.

Not on Public Display - The Model 72 prototype should be visible undergoing extensive testing at Mojave and at other required sites. However, it is not on public display at the RAF facility since it is housed at a remote hangar. Grizzly has not been and will not be our highest priority - we will continue to concentrate on our homebuilt programs, the Model 61 Long-EZ and our new self-launching sailplane, the Model 77, Solitaire.

OSHKOSH 1982 - Those of you who will be making the pilgrimage to Oshkosh this year should note that the Hospitality Club banquet will held at the Anchor Inn on Sunday August 1st 1982, not on Wednesday as it has been in the past. The annual banquet is limited to Hospitality Club members or to those actively flying a VariEze or Long-EZ. For

information on the Hospitality Club write Don and Bernadette Shupe, 2531 College Lane, Laverne, CA 91750.

Camping at Oshkosh - Those EZ pilots flying in and wishing to camp can reserve a camping trailer (sleeps 4 to 6) which will be parked in Paul's Woods the week prior to the flyin. The cost is $150 per trailer, payable at least one month before August 1st, plus cost of registration and camping fee. There are only 8 trailers available, and reservations are on a first come, first served basis.

Contact: Nat Puffer,
2182 North Payne Ave,
St. Paul, MN 55117

Irene "Mom" Rutan, official historian for the VariEze Hospitality Club, requests that all VariEze and Long-EZ pilots send her a photo and information on their airplane as soon as possible after first flight.

VARIEZE/LONG-EZ CLUBS

Jerry Gruber, who recently flew his beautiful Long-EZ, has offered builder assistance to anyone in his area. Contact Jerry at 401 Aspin Dr., Elkhart, Indiana 46514

John Steichen of Downers Grove, Illinois would like to hear from builders/flyers who would be interested in some form of Great Lakes or Midwest hospitality activities. John is willing to organize a winter or spring flyin/drive in. Contact

John Steichen (N27EZ),
Brookeridge Air Park,
960 86th Street,
Downers Grove, Illinois 60516

SAFE-T-POXY - REACTIONS, ALLERGIES

It has come to our notice that quite a number of builders seem to be suffering from some form of reaction to the Safe-T-Poxy. We are very interested to know the present scope of this problem, since initial results in 1978 showed that reactions were very rare. If you have had any kind of reaction to the Safe-T-Poxy, please send us a report with a brief description of the reaction, and how long you had been working with the material before you noticed the reaction, whether or not you were using any form of protection, gloves, Ply 9, respirator etc. We will correlate this information and work closely with the manufacturer to see if a change has occurred or if improvement is indicated. We will report on our findings in a future C.P.

FOAM PREPARATION

Although we have had this correction in at least two previous newsletters, some builders are still not using micro slurry. ALL foam should be slurried. Disregard ANY and ALL statements in the Long-EZ plans that say not to use slurry. By slurring the foam, you will be able to do a better quality, lighter layup, in less time.

Slurry fills the broken cells on the foam surface. After spreading slurry on, wipe off excess with the squeegee to that only a thin film is uniformly spread over the entire part. The construction video tape is a good reference for good slurry technique. If in doubt, send RAF a sample of your work for our comment (include a SASE, of course).

If you have already made some of your parts without slurry, it is not necessary to remake them, provided you have met the dryness criteria. If they are very wet, or too heavy, you might consider doing them again, however lack of slurrying is not cause for structural disqualification.

PARKING YOUR EZ
It does not seem possible, but there are still VariEze and Long-EZ builders out there who apparently are not aware of the fact that this configuration of aircraft will fall over on its tail if it is left unattended while the nose gear is extended. The pilot is required in the front seat to balance the airplane to the correct cg. Should the pilot climb out and let go of the airplane, it will fall over on its tail, and this can result in a broken prop or at least damaged winglets. This condition is unavoidable. The main gear position is a direct function of rotation speed. Ballasting the nose to overcome this will result in unacceptably long take-off rolls, and a very difficult airplane to handle on the ground. This is the main reason that the nose gear retracts. This allows you to park the airplane nose down, which is a very stable way to park and avoids the requirement for a wheel chock when untied in winds up to 35 knots.

BUILDER-INITIATED CHANGES
This is an item that needs to be put into perspective, since we often answer questions and often observe activity that we consider questionable. First, we do recognize that you are the manufacturer of your aircraft and that if you do not agree with us on specific details you have every right to modify, redesign, substitute etc., on your aircraft and to then take the risks of trying something new and untested. We do recommend only that which we have tested, since it is the only configuration we know is adequate and, by our own experience we can report on and support.

Any builder (at least U.S. builder) has the freedom to build his own aircraft exactly as he sees fit. Changes he makes will be opening up new areas not substantiated by test. We have no argument with this. However, if he makes recommendations to other builders on a change that he likes, but has not verified by test, he should realize that he may be liable for loss or injury caused by that change.

If, for example, you recommend a larger engine or a substitute of an inferior foam core to someone else, without fully qualifying and testing the many design changes that may be required, you must remember that those builders are now counting on you to be right and that your responsibility is then extended beyond your own risk with your own airplane.

MODEL 73 TEST PROGRAM COMPLETED - The RAF Model 73 is a scaled flight demonstrator of Fairchild Republic's proposal for the Air Force's Next Generation Trainer (NGT) program. In early 1981, Fairchild Republic contracted Ames Industrial Corp. (builder of the RAF Model 35, AD-1

skew-wing jet) to build the scaled flight demonstrator. Fairchild supplied accurate lofts of the external shape of the NGT design. Ames hired RAF to design the structure and systems and to conduct the flight test program. The scaled demonstrator is 62 percent of the size of the full scale aircraft.

The design and prototype construction effort took eight months. The aircraft was shipped to RAF in early September 1981. Within eight weeks RAF accomplished all the following tasks: flew four qualitative flights, coordinated the installation of a telemetered instrumentation system, flew 14 stability and control flights, developed and tested a spin recovery parachute, measured and ballasted the three-axis moments of inertia, developed a fuel transfer system for cg control, designed and incorporated several modifications, reduced, analyzed and presented all flight test data, wrote the qualitative flying qualities results, conclusions and recommendations, prepared a 220-page test report and an oral/video tape/slide presentation of the results. Working on a tight schedule, the final report and presentation was presented to Fairchild seven days after the last test flight. The use of the manned, scaled flight demonstrator produced higher quality data than other methods, particularly for areas such as spin susceptibility and departure recovery. The scaled flight demonstrator was built within a schedule and cost framework that compared to conventional static-only wind-tunnel programs. However, the added benefits of dynamic stability data and pilot qualitative information resulted in considerable improvement in the value of the findings. The structure of the Model 73 is the moldless composite sandwich method, using oriented uni-directional carbon fiber or fiberglass for facings and spar caps and rigid closed-cell foams for core.

NEW COMPANY, SCALED, INC. TO DO RESEARCH PROJECTS
Since the successful completion of the Fairchild 62% NGT program in November '81 there has been a great deal of interest in RAF's capability to design, develop, fabricate and flight test new aircraft concepts at low cost and short schedule. Because of this interest, Herb Iversen, General Manager of Ames, the company that built the NASA AD-1 and the Model 73, is forming a new company to deal exclusively with this new type of business. Burt will do the design work and the flight testing for the new company. No changes are planned for RAF. RAF plans to continue to support builders of RAF-designed homebuilts and to develop new designs for homebuilders.

The new company will be called SCALED, Inc. The SCALED is, in fact, any acronym for "Scaled Composites: the Advance Link to Efficient Development". Pat Storch spent several late nights and the better part of a carafe of white wine to come up with that name!

SCALED will be based on Mojave Airport next door to RAF. The new facility will conduct the entire program of contracting, design, fabrication, testing and reporting. Proposed customers for SCALED include any agency requiring aerodynamic, systems or structural research data early in the development cycle. To date, proposals include next-generation general aviation designs, commuter airliners and military applications.

SCALED INC., NEEDS HELP - SCALED Inc. who will be involved in designing, building and testing proof-of-concept demonstrator aircraft

similar to those RAF and AMES have collaborated on in the past are looking for charter members for their new staff. We're currently looking for some shop help, a computer fanatic, a flight test instrumentation technician and a French speaking secretary/receptionist (word processing experience helpful). Also needed turbo-jet, turbo-fan engineer/manager. Needs to have 10 years experience with turbo-jet/APU, overhaul/repair.

If you are more concerned with interesting, challenging work than in civilization and culture, you might consider a move to our Mojave Desert to get in on some real stimulating projects. Send resume to:

Herb Iversen

Bldg 13, Airport
Mojave, CA 93501

CP31, Page 3

BUILDER HINTS

We have recently tried an excellent substitute for featherfill. This product is a two part polyurethane primer filler and is manufactured by: Sterling Lacquer Mfg. Co, 3150 Brannon Ave, St. Louis, MO 63139 (314)776-4450. Contact the above for a local distributor in your area. Sterling primer filler (part # U-1761 and U-1762 and U-1014 thinner) is a high solids primer with excellent sanding and film thickness building properties. We have used it with up to 20% by volume mixed with micro balloons and were still able to spray it. It can also be brushed on. The good news is that it cures very rapidly, 45 minutes to 1 hour and sands nicely to contour. It also adheres very well. The bad news is the price. This is an expensive material, the price seems to vary considerably depending on where you are located.

When applying Spraylat to your canopy for protection, be sure to get a good thick coat, preferably 2 or even 3 coats. This will make it much easier to remove. Also, if you spill epoxy on the Spraylat, wipe it up with a paper towel before it cures. If it cures, it will not damage the plexiglass, but it does make it very difficult to remove the Spraylat locally.

A 3M part #7770 Clean'n'Strip brush, mounted on your drill really does a super job of carving the R45 dark blue foam. As an example the bottom can be carved and ready to glass in only 45 minutes. Thanks to Don Jehlik for this one.

When knife trimming, hold a strong light under the glass overhanging to more clearly show where the edge of the foam is.

Long-EZ Clarification

Section I, page 19-8.
Lay up #5 is one ply of UND per leg of the "V" layup. (2 plies over the shearweb face).

Caution - Damage From Brake Heat

Do not conduct your taxi tests, high speed taxi and first flights with wheel pants installed. You will be using far more brake during this

period than is normal. See Long-EZ Owners Manual, page 41, under low speed taxi.

If you do have wheel pants installed, it is possible to generate enough heat buildup to soften the main gear strut and cause it to sag/fail.

Long-EZ and VariEze - Glue a piece of fiberfrax on to the outboard face of the main gear strut to protect the strut from local heat radiation from the brake disc.

If your control sticks have any lateral slop, try substituting AN174-20 close tolerance bolts for AN4-20 pivot bolts in the control handles.

Balancing Long-EZ ailerons. Several builders have reported having a problem in this area. If you are having difficulty with this, double check your hinge pivot is exactly correct, in most cases this has been the problem. When building your wings, keep the aileron as light (almost dry) as possible. Install the balance weight in the correct relationship to the hinge. Some builders are getting the weight too close to the hinge. See Section I, page 19-14 for full size sections.

When you install your wheels, spin them and check the disc for runout/wobble. It should run true, within .010". If not true it can force the brake caliper piston back inside the caliper, and then you may have to pump the brakes once or twice before you get a solid brake.

If you are experiencing gear "walk" or shudder as you roll out to take off or land, particularly as you brake to slow down, you should balance your wheels and tires. An out of balance condition that may not be noticeable on a factory built, may be objectionable on a VariEze or Long-EZ due to the relatively flexible gear strut.

Many builders have enquired about the relief tubes that are installed in N26MS and in the prototype N79RA. Here is a brief description of how we did it. We used 5/16" ID x 3/8" OD plastic line from the local hardware store. We left it about 2 ft. long in each seat and ran it down the length of the fuselage through the aft seat bulkhead to the trailing edge of the gear. Then is was run down the trailing edge of the gear and left long enough at the bottom of the gear to protrude out of the wheel pants. The brake line was run down aft of the relief tubes on the trailing edge of the gear, to help fair in the gear strut. **SKETCH OMITTED**

After you install your wheel pants, drill a 3/8" hole in the aft bottom of the wheel pant and run the relief tubes out about 1 1/2 " through this hole. **SKETCH OMITTED**

We coil up the excess 24" or so and stow the coil in the front seat on the left side behind the static port line, and in the back seat, under the right console. To use the relief tubes, uncoil them and plug a rectangular plastic funnel into the end of the tube. The funnel is kept in a zip lock bag in the center section spar. To keep it and the relief tube clean and fresh, rinse out with a mixture of vinegar and water. **SKETCH OMITTED**

We had always had a small oil slick on the cowl from the breather on our Long-EZ, not enough to notice any oil loss on the dip stick, but

enough to be unsightly and aggravating. We cured this by running the breather line forward and up to the top of the forward engine baffle, looping it around and back down and aft to the normal breather exit shown in Section IIL. This necessitates using about 4 feet of 3/4" ID x 1" OD hardware store vinyl tubing. This is tied to the forward baffle brace and the engine lift point. To assure that this tube would not kink and pinch closed, we installed a 5/8" OD screen door spring, stretched out til the coils are 1/2" apart, inside the vinyl tube. This works like a separator, and even after a long flight, we have a clean cowl.

Caution - When floxing the top of your VariEze fuel strakes into place, be careful that excess squeeze out of flox does not drip down onto the screen, drip through and fall onto the open end of fuel pick up tube.

Caution - Exhaust system modifications, particularly those causing large bumps on the lower cowl (like cross-over or muffler-under-engine) can result in a performance loss as great as 15 mph due to aerodynamic drag, caused by airflow separation aft of the cowl modification.

Caution - Nose gear crank systems on both VariEze and Long-EZ, must have the two NG14 heavy wall aluminum tubes installed. These parts may not have been included in your nose gear actuator assembly from Brock.

Caution - Nat Puffer would like to share a problem that he has run into. He bought an engine mount and a cross over exhaust system from a supplier (not one of RAF's designated suppliers) and has had problems. The supplier has refused to make good or to refund. Nat is a member of the VariEze Hospitality Club, and anyone interested in the exact nature of his problems should contact Nat Puffer.

Caution- Oil pressure line should have an orifice fitting at the engine end. We have not been able to find a source of these fittings, but we have made up an acceptable substitute by making a small plug for the pipe thread end and drilling a #60 hole in it, installing it in the AN fitting and staking it into place.

Warning: Possible fatigue or installation failure of aluminum fittings in engine plumbing. We have had failure reports of aluminum fittings that support hoses or transducers on the vibrating parts of engines. This is a very serious concern, requiring us to recommend a grounding change that replaces certain fittings with equivalent steel parts. Refer to the plans-changes section of this newsletter for the new fittings. Do not fail to install the new steel parts, a failure can be fatal.

PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting

the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

VariEze and Long-EZ

Owners Manual
Under engine failure, add "CAUTION, in weather conditions where carb ice is likely, descents should be made with as high a power setting as possible in order to keep the maximum available carb heat. Descent at idle power will allow carb heater (exhaust system) to cool down such that inadequate heat will be available should the carb ice up. This is particularly true when using any of the Continental engines".

VariEze Plans Changes

Owners Manual, Page 39
Under annually or each 100 hours, add - Jack aircraft up so that both main wheels are clear of the ground, and check for attachment wear by moving each wheel fore and aft - there should be no apparent excessive movement. If wear is present either bush the aluminum extrusions or drill out to 5/16" for AN5 bolts.

Fuel Cap Retention.
Geoff Danes from Australia, reports a lost fuel cap experience, with a cap secured to the cross wire by a short length of brass bath tub plug chain. Contrary to our previous fears of the cap flailing and damaging the top surface of the strake, very little damage occurred. Thus we are recommending that all fuel caps be attached to the cross wire with a length of brass "hardware store" chain as shown. Keep this chain as short as practical.

MAN/GRD 25 hours

VariEze oil pressure line - if you have substandard fittings and hose on your system, change it to that shown on page 8 of this newsletter.

MAN-GRD 25 Hour
At each end of the flex line from the gascolater to carburetor (see page 4 of this newsletter). Remove the following aluminum fittings:

AN822-6D	1
AN816-6D	1

Install the following steel substitute fittings:

AN822-6	1
AN816-6	1

Long-EZ Plans Changes

LPC #88 MEO, Section I, page 19-16.
Part #CS127 is made from .032 2024T3 aluminum.

LPC #89 MEO, Section I, page 9-3.
Sketch on lower left of page shows brake line run between the gear strut and brake disc. This is incorrect. The brake line must run around the inboard face of the strut. This puts the strut between the brake disc and the brake line.

LPC #90 MEO, Section I, page 20-4.
Step 6, says see Section III, this should read, see page 22-3.

LPC #91 MEO, Section I, Chapter 19.
Covers for the access holes, three each side, for wing attachment can be fabricated out of .016 aluminum sheet, painted to match you airplane. To install, stick over the hole using a small bead of RTV (silicone, clear silicone rubber sealant by Dow Corning is best). The covers should be taped or weighted into position and left to cure for at least 24 hours. They are water-tight and keep the rain out of the attach area. If you need to remove them later, a razor blade will easily cut them loose. **SKETCH OMITTED**

LPC #92 MEO, Section IIL.
Oops! We neglected to cover installation of the ram inlet scoop. This prefab part should be installed onto the bottom cowl, permanently. It is floxed into place, and has a flush "pop" rivet approximately every 2" around the flange. After cure, one ply of BID is layed up inside lapping 1" onto the cowl and the ram inlet.

LPC #93 MEO, Section IIL, page 36, bottom left.
AN823-4D should be AN816-4, also aeroquip 496-4 should be 491-4.

LPC #94 MAN-GRD, 25 HOUR.
Remove the following aluminum fittings:

AN822-6-2D	2
AN816-6D	2
AN823-6D	1
AN912-1D	1
AN823-4D	1

Install the following steel substitute fittings:

AN822-6-2	2
AN816-6	2

AN823-4	1
AN823-6	1
AN912.1	1

Refer to the adjacent circled items from Section IIL, page 36 to identify effected parts. Make the appropriate changes to Section IIL, pages 13, 18 and 37.

ACCIDENTS AND INCIDENTS

The CP Newsletter reports accidents and discusses their conditions and causes, for information purposes for all operators. We have always investigated accidents in the interest of determining information that we can disseminate to you to prevent recurrence. It should be recognized in our discussion of accident conditions or causes that generally this information is preliminary since it is published before the availability of the FAA accident report.

Long-EZ - Runway And Visibility

A Long-EZ crashed on takeoff from a small Minnesota airport. Conditions were clear, it was dark (about 1 hour before sunrise),the runway was hard surfaced, but covered with ice and snow, some large lumps of ice up to 4" thick. The runway was 2,000 ft. long and ended near the edge of a lake. The aircraft was in excellent condition with approximately 60 hours total time, with 5 hours flown the previous day. It had been hangared and had no frost on the wings, however an eye witness reported that the canopy was frosted over on the inside such that he was unable to see the pilot just before take off. The pilot commented that it was no problem because his experience was that the canopy would clear as soon as he had some speed. It appeared from wheel tracks in the snow that he had a very extended takeoff roll, in fact rolled virtually the full length of the runway. He struck several hard lumps of packed snow/ice with nose and main wheels, which probably slowed him down. When he lifted off he did not climb enough and flew into the tops of some small trees of the end of the runway. The left canard and left elevator were torn off at this point, which caused the airplane to roll left. The left wing then struck the ground and was broken off at BL57. The airplane rolled inverted and crashed into a frozen swamp on the edge of the lake. It then slid over a small embankment and broke through the ice coming to rest in four feet of water. The fuselage remained essentially intact, however the pilot was killed instantly.

The cause of this accident appears to be a combination of several things. 1) Takeoff attempt on an uncleared runway with snow and lumps of ice. 2) Frosted canopy probably restricting visibility. 3) Total darkness with lake at end of runway resulting in "black hole" visibility effect at lift off, causing disorientation. As is often the case in accidents, one problem could probably be handled by an experienced pilot, but a combination of the right conditions can be enough to result in disaster.

Composite Structure Fire - There were no instances of fire on any VariEze type structure in over 200,000 flight hours of operation - until last fall. Here's the report from Ron Walter:

"I pulled in front of my hangar, shut down the engine and put the plane on its nose. Looking back I noticed flames coming out the back and proceeded to get an extinguisher to control the flame. This was to no avail and resulted in completely destroying the plane within approximately 12 (more) minutes."

A fellow VariEze builder arrived on the scene after the entire engine area and cowl were involved and he offered the following, cautioning that some is conjecture.

"At runup area engine did not sound normal. After several tries at runup he taxied back to hangar parking. Time of run was about seven minutes. On shutting down the engine with the idle cut off he noted smoke from engine compartment. He retracted the nose gear, got a small fire extinguisher and emptied it into the fire. By that time however the fire was out of control."

"Fire definitely was well along in the engine compartment when aircraft was shut down. It might have been arrested if fuel valve had been closed when smoke was detected and fuel burned through engine. Initial cause was stuck float in carburetor which kept feeding fuel to point of overflow (conjecture)."

"The aircraft was headed west and wind was from 240 degrees about 3-5 knots. This fact inhibited the fire somewhat but I was surprised at the slow propagation of the fire, about 2 to 3 inches per minute forward on both wings. The heat softened the upper wing strake to the point that when the gas in the tanks ignited there was only a large "poof" - no contained explosion or any shattering. Even at this point neither the outer wing spars nor the center section box, showed deformation. Obviously they were getting soft but no sag. Within the next minute the fuel from the tanks intensified the fire to where everything melted down and completed burning forward to the front cockpit. At this point the main gear softened and gave up. Fire truck arrived and put out remaining fire.

Findings: Carburetor completely melted down to point of distortion - recognizable, but that's about all. Fire wall took a lot of heat before allowing fire to progress forward. Fuselage tank failed through sight gauge first. I could not tell whether the fuel feed line from the tank to the shut off valve had softened and burned feeding the fire. Engine mount distorted but intact. Top of wing tanks burned but bottom remained intact until almost complete collapse of main gear."

Ron also shared with us a poem written after the fire by his wife.
"You were the diversion he needed in times of stress.
You were solace to him when he was not at his best.
When the world was to much for him to cope,
He turned to you, and you gave him hope.
In the wee small hours when sleep wouldn't come,
You were there - always something to be done.
You and he saw the world from a different view,
When you soared together to the distant blue.
You're gone now - no more obsession.
Only memories left - the only possession.
You were the joy and the pride of his life.

I can't fill the void. I'm only his wife".

VARIVIGGEN NEWS
Bertil Fornen, from Stockholm, Sweden sent in a few photos of his Viggen project and it really is going to be something. Bertil has installed a full IFR panel, has a neat electric reflex, and has completed the installation of the main gear retract system, which is the same as that on N27MS. His nose gear retract mechanism uses a slick little motor driving the gear up and down through a toothed belt. Looks like an excellent idea - let us know how this works out, Bertil.

George Craig called on us here at RAF last week and showed me some photos of his excellent Viggen, which is coming along well. George finally got his main gear operating and is very satisfied with it. George had problems getting the correct springs to help pull up the gear and tells me that anyone wanting a set of springs to do this job should order them from:
Stock Springs Co., (415) 828-0373
Talk to Truman Allen. You will need 8 springs (4 on each side) .062 wire dia., 302 type stainless, 1/2" OD x 11 5/8" free length. George paid about $35 for all 8 and reports that they work great.

Arthur Schwartz reports that his Viggen is running like a dream and he now has 123 hours on the tach. Arthur is planning on installing the worm gear main gear system soon, up till now he has been flying with the main gear down and nose gear retracted. The cable system is just too unreliable. Reference CP 26, page 9, when Arthur's Viggen had the right main collapse while taxiing. There is a lesson here, to my knowledge there has not been a single Viggen that has had a satisfactory main gear using cables or chains. Every one to date has had one or more failures. The worm drive system as used on N27MS has been 100% successful so far, and it is now the standard recommended system.

I have not had a written report from Len Dobson, but he called a few weeks ago with the heart breaking news that he had collapsed the gear on his ship. Briefly, he landed on a narrow runway, with a strong cross wind, and drifted off into soft sand or mud, this tore off the nose gear and folded up one or both mains. Damage to the airframe is fairly extensive, but Len is unhurt (physically). He plans on rebuilding and will keep us posted.

FROM THE BUILDERS

Dear Burt, Dick, Mike and Sally,
We can't thank all of you enough for your generous support and help in our flight test of our Long-EZ N7LZ. We (son Dean, wife Joan and I) worked on this project for slightly under one year and we couldn't be more pleased with the resulting product. The Long is fully equipped with R-NAV and transponder for easy cross-country cruising; and, with Burt's unique design, it performs like no other two place aircraft for this purpose. It weighed in at 874 lbs. without wheel pants or spinner and apparently is the 12th Long-EZ to fly. Mike's gracious offering to fly the first flight was more than we could expect, but he went further

and checked out Dean. Since I'm only a student pilot, Dick, who is a CFI, checked me out. Burt personally inspected the craft and pronounced that it would fly straight and true and it did! The required 25 hours of test flying was completed within 5 days, so we were on our way home only a week after we arrived. The only problem encountered was a need to correct a slight cusp on the aft edge of the elevators and rebalancing them. Performance matched or slightly exceeded the owners manual values.
Thanks again,
Bob, Joan, and Dean Hansen.

Dear Burt,
VariEze N774 lifted off at Tehachapi airport on November 12, 1981. The duration of the flight was for 35 minutes and everything went well. I had two rides previously in VariEzes, one with Bruce Tifft and another with Richard Clark, so the feel and performance was about what I expected. At completion it weighed in at 638 lb. It has a C-85 without starter, standard instrumentation and a B & T prop. At 7000 ft. 2650 rpm it indicated 152 mph. It flies straight and level, hands off and stalls at 65 mph with no tendency to drop a wing. From the moment I saw N4EZ about four years ago I wanted to build this airplane and to say that I am pleased and proud of this little bird is an understatement. The highest tribute that I can pay to your expertise and builder backup is to say that after 46 years of active flying, 37.5 with TWA, it was one of the highlights of my career to fly my own personally constructed aircraft. I want to thank you, Mike Melvill and your entire crew for their patient help and encouragement which allowed me to enjoy this experience.
Sincerely, Bob Cummings, Tehachapi, CA

EZ Autumn Escapade - by Bruce and Bonnie Tifft.

Flying U.S.A. during the autumn season is truly spectacular, as we discovered for ourselves on our recent almost 7000 mile trip across our glorious country. Fantastic, beautiful, breath-taking, magnificent, etc... etc..., were the only words we "almost native" Californians could find to describe the awesome spectacle of the colorful trees, shrubs, flowers and scenery as we visited the various states on our journey to and through New England. Someone up there was really looking after us as far as the weather was concerned because we found ourselves in crisp, clear, sunshiny blue skies almost all of the trip; only a few days of scud-running out of the three weeks we were gallivanting around the country. Not only were we delighted with the beauty of these United States at this particular time of the year, but of the marvelous assortment of friends, new and old (not age-wise of course), that we met along the way. We almost wore out our Hospitality Club list from using it so much. It was easy calling on the members that we had met previously at various flyins since we felt we knew them already, but it was a little more difficult to call up "strangers". However, what we found very quickly was that none of us that have these super flying machines, or are in the process of building them, are strangers. We were welcomed in each and every instance like long-lost friends or relatives. There is a tremendous, warm bond between the people with these airplanes, and we thoroughly enjoyed our stay with each and every one of the Hospitality Club members and also our B & T customers that we visited. It was great for us to have the opportunity to get acquainted with all these interesting people, and they seemed to

enjoy the chance to swap EZ stories, get building hints, chat about the flyins, etc. Of course, back-seat checkout rides were a must for all the would be EZ pilots and it was such fun to see the reaction from the fellas and gals who have never had the thrill of flying in a EZ before. They were so excited and enthusiastic about the wonderful flying characteristics of the EZ. It's especially fun to get this reaction from the high-time pilots who have flown lots and lots of different kinds of aircraft over a period of many hears. They are as impressed as the brand new pilot. It's really rewarding for us to share this experience. Our journey took us up to Salt Lake City, UT; over the wilds of Wyoming (where we had the opportunity to check out how service roads compare with runways - however, that is another looong story what we will share some other time); into the Plain states and a stop in Lincoln, NB; up into Minneapolis/St. Paul, MN; around Lake Michigan to Lansing; over across Canada and Niagara Falls to Utica, NY; down to Hyannis, MA and Cape Cod Bay where we had our only "crash" for the trip - Bonnie falling off her bicycle on Nantucket Island; up to Camden ME; (missed our visit to Vermont since weather was reporting two inches of snow - burrr); down the southern route and stop in Bruce's hometown of Allentown; PA; on down into Illinois, Missouri, Oklahoma and into Texas, New Mexico, Arizona and back again to California, with a stop at Mojave to relate our adventures to the RAF crowd. We arrived home with six rolls of slides and an enormous collection of memories to hold us for at least another year (well, maybe six months). We have found that these EZ adventures are becoming habit forming and eagerly look forward to planning and experiencing the next one. Our sincere thanks to Shirl and Diana Dickey, Jo and Carlye Reinmuth, Nat and Shirley Puffer, Buzz and Ann Weatherly, John and Fran Kevern, Gary Price, Joe and Fran MacDonald, and Harris and Cleta Sue Howard for their warm, friendly hospitality. As Harris and Cleta would say "Y'all come visit us sometime".

NOTE FROM B AND T PROPS
Bruce recently retooled his prop drilling jigs and asked us to inform anyone with a B & T prop, shipped prior to January 1, 1982, if you are checking balance, to use only the 2 1/4" dia. hole, do not use the 3/4" through hole, since it may not be concentric. Props shipped after the above date, you can use either the 2 1/4" dia. hole, or the 3/4" dia. hole or both to balance the prop. Please don't hesitate to contact Bruce or Bonnie if you have any questions at all concerning your prop. 805-649-2721

SHOPPING
Task Research - Fuel/baggage strakes are in stock for immediate shipment. Special on the next 25 orders only. Ribs and baffles will be included with strakes for $884.

John Frilling, who sells a set of plans to make a light weight alternator, as reported in CP 26 page 11, has recently moved. John's new address is:

John Frilling,
743 Annoreno Road,
Addison, IL 60101

Find that elusive CP article! Index for Canard Pushers #16 through #29 now available. $3.00 per set, 10 pages.

HOT WIRE SET UP - The homebuilt hot wire set up that was described in CP 29, page 8, works fine, but many have had problems locating the parts. Vince Golden has kindly agreed to provide the transformers for those who can not locate them locally. Contact Vince at: Mike Quinn Electronics,
Bldg. 727 Langley Street,
Oakland Airport, CA 94614
415-569-1539
Vince will send you the transformers and modification parts by UPS for $7.50 plus $3.50 shipping.

Rusty Foster has developed a very nice space saver console that fits on the right side above the stick. This prefab panel will fit into a VariEze or Long-EZ. See photos. This looks like an excellent idea, is light weight, and a practical method of getting more room on your instrument panel for avionics/instruments.
Contact: Rusty Foster
P.O. Box 4273
Ventura, CA 93004

Due to some confusion over AN versus MS hardware, we have complied a conversion chart which should help clarify things. Our thanks to Bud Meyer of Wicks Aircraft for assistance in getting this chart together.

CP31, Page 8

A Chino Valley area Long-EZ club for beginners, those in the middle and those finished. Let's get together and share some of our ideas and helpful ideas and helpful hints.
For more information please contact:
Kim Prout, 3801 Carlos Court, Chino, CA 91710 (714)628-1403
or Paul Prout (714)621-0060
Everyone welcome.

Our thanks to Gerry Grueber for sending in these nice photos showing the fuel/baggage strake construction.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Jig "tables" in place ready to build bottoms of fuel/baggage strakes on a Long-EZ.

Fuel/baggage strakes with bottoms layed up and ribs micro'ed into place. Be sure to do almost "wet" layups inside your tanks to eliminate the chance of leaks later on.

Ribs, layed up, will be knife trimmed later. The notched out openings should be painted with pure epoxy. No need to do a glass layup on the edges of any of these holes.

View of the inside of the top of the fuel/baggage strake. Note that this foam part is supported by a lumber frame bondo'd to the outside.

Fuel/baggage strakes floxed into place for cure.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Size comparison 3.40 x 5 - 4 ply and the new 11 x 4.00 x 5 - 6 ply. The new 11 x 4.00 x 5 - 6 ply has shown excellent durability in service. We strongly recommend it or the 500-5 for the heavier Long-EZ. Also, it is the best VariEze tire size.

These are the new RAF jacket patches - the general logo on the top and small Long-EZ on the bottom. We also have VariViggen and VariEze bottom patches. See page 1 for prices.

Grizzly, Model 77, on her first flight, with Mike Melvill at the controls. Polaroid photo by Pat Storch snapped just before this newsletter went to press. The Grizz matched the stability predictions and has exceeded performance estimations.

This photo clearly shows the 7 to 8 degree camber of the Long's gear with a light load.

OK, which way to a runway! Roger Johnson's Long nearly complete.

First-released photo of our Model 77 Solitaire self-launching sailplane. The fuselage shells were lofted and plotted on our Apple II micro computer with lines optimized for the thermaling design point. The engine is in the nose, with the prop extending out of the forward fuselage.

Rusty Foster's space saver side panel for Long-EZ. See page 8.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

Check items desired.	Price, includes first class mail	Overseas, Airmail - U.S. Funds only

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 32. If you are building from 2nd Edition plans you must have newsletters 18 through 32. If you are building a VariEze from 1st Edition plans you must have newsletters from 10 to 32. If you are building a VariEze from 2nd Edition plans you must have newsletters from 16 through 32.

A current subscription for future issues is mandatory for builders, as this the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca. approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 on Saturday. Closed Sunday. If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to flyins. When arriving at Mojave by car turn east at the Carl's Jr. restaurant to find the airport.

When writing to RAF send a stamped, self addressed envelope along if you have any questions. If you are placing an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed up your reply.

Saturday Demos. - Every Saturday (except when gone to airshows) RAF conducts a demo at our shop at the Mojave Airport. We start the presentation/discussion at 10:00am each Saturday with flight demos of our experimental aircraft at approximately noon (weather permitting).

RAF Activity
Since CP 31 has involved development of structure, controls, landing gear, and propulsion system for our self-launch sailplane, the Solitaire. In addition, our Grizzly research STOL aircraft has completed it's basic land-plane flight test development effort. Due to a higher priority on the Solitaire and to some consulting commitments we are not pursuing the Grizzly amphibious floats at this time. We may begin that this fall.

The Solitaire development was delayed by propulsion system problems, however a redesigned configuration is now running smoothly in our test stand and we expect to be into flight testing by mid May.

RAF has made a "few" covers of magazines since the beginning of '82. The following is a list. The first three are photos taken by our own RAF photographer, Pat Storch.

Homebuilt Aircraft - May

SEMINAR IN FLORIDA
In February Burt and I flew to Miami, Florida (in a Lockheed L-1011) where Burt was the speaker at EAA Chapter 37's annual banquet. I was lucky enough to tag along, and I must say I really enjoyed the banquet. The food was good, Burt's talk and slide show, as always, was great and being in the company of so many VariEze and Long-EZ builders and flyers was neat. Charlie Gray, a Long-EZ builder organized the whole affair, and did a super job. A really nice touch was that each person at the banquet received a water glass, with a Long-EZ printed on one side and the Chapter logo and date printed on the other.

The next morning Saturday, Charlie drove us to the Fort Lauderdale Executive Airport, where Burt and I gave a composite seminar to about 300 people. At least two Long-EZs and two VariEzes flew in and I was pleased to be invited to fly Jack Fehlings gorgeous VariEze "Yellowbird". Burt and I spent a couple of hours talking to builders, before the seminar, and several things were noted on both Long-EZs that were there. Smooth contour on wings, canards and winglets is really important if you are to get the performance you expect. Paint stripes along the leading edges of wings and canards are only acceptable if there is no masking tape joggle. A joggle like this can trip the boundary layer and transition good, low drag, laminar flow into high drag, turbulent flow. NASA tests on our Long-EZ has shown that destroying all the laminar flow can cost you up to 11 knots!

Prior to the seminar, Charlie Gray had got hold of a reject canard that we looked at and Burt agreed that it should not be installed on an airplane. We decided to do an informal static load test to destruction. So we called for people weighing about 175 lb. With Burt positioning each person for correct load distribution, we proceeded to try to fail the canard. We got 18 people (not an easy task, very little room!) on it before we finally got a few minor cracks. At this point, Burt calculated we had 11.54 g's on it, and it still would have got the airplane home. It did not fail catastrophically. Someone must have photos of the 18 people on it. We didn't get one, unfortunately.

The seminar went well, we both enjoyed the opportunity to answer questions, look at parts, and do some hands on, hot wire cutting, layups etc. When we went back to Charlie Gray's home, both of us were a little "hoarse" but it was fun. Sunday, on the way to the airport, we visited a couple of Long-EZ projects, wish we could have seen more

of them. There are a lot of Long-EZs under construction in the south of Florida. Thanks to Charlie and his wife Betty for showing us such fine hospitality. Charlie should be flying his Long before to long.

SCALED COMPOSITES, INC.: HELP PART II
Many thanks to the people who have submitted resumes in response to the ad in CP 31. The response was more than we expected. We haven't yet selected people for the positions offered but will have made the selections by mid to late summer for hiring in September. All those who wrote to us will be contacted, so please be patient with us. SCALED has purchased a new Computer Assisted Drafting package and we are looking for an enthusiastic engineer/draftsman to use it. The system is based on the Apple II + microcomputer and runs in PASCAL, so some experience there would be helpful. We also need a bookkeeper/accountant (any MBA dropouts out there?). The receptionist/executive secretary position is still open for the right person, the French speaking requirement is no longer necessary but the word processing experience is.

NEW RAF POSTER NOW AVAILABLE. SEE BACK COVER

MIKE & SALLY'S LONG-EZ
N26MS has been spending more time in the hanger than usual due to bad weather, while the weather in Mojave is almost always acceptable it certainly is not in Tehachapi, so during the two to three months of winter type weather, we have been driving, and what a pain that is! On top of that it actually takes more fuel to drive our Honda Accord to work and back, than it does to fly the Long!

Even so we have managed to put some time on her, she is just over one year old and has 320 hours total time. I did an annual inspection last month and found very little, I adjusted the rudder travel, relined the brake shoes, changed the oil, topped off the batteries, checked brake fluid level and that was about it. Engine health is excellent with compression like new on all four cylinders.

The airplane has proved to be exactly what I had hoped, a low maintenance, high utility, high speed, economical cross country airplane. I have been testing a small electric cabin heater for the past month or so. This heater is STC'd for any aircraft, and came to me from Steve Franseen, 1245 S. Tennyson, Denver, CO 80219. Steve is a Long-EZ builder and is the distributor for the heater. Contact Steve if you are interested.

The heater I have is a 12v 16 amp heater, with an advertised capability of heating a 50 cubic foot area. On the ground, static it is much more that you need. In the air at a normal cruise speed around 160 knots true, in my Long-EZ, it is marginal with an outside temperature of -14 C. This is primarily due to the many air leaks that I have, around the elevator tubes, the nose access hatch, etc. I am sure that with close attention to sealing the nose of your Long-EZ from all leaks, this little heater will do an adequate job. I am going to be testing a 24v 16 amp heater, which has an advertised capacity of 80 cubic feet, in

the next few weeks and will report on the performance in the next CP. The heater is well made, has a built in fan and safety cut out. It is also internally fused. It completely eliminates the problem of carbon monoxide contamination, and is easy to hook up. I installed mine in less than an hour.

I have also recently installed a Compucruise and flo-scan fuel flow transducer. I elected to use a flow-scan series 100-A, which has a range from 1.5 gph to 15 gph. It is a real kick to fly with this gadget on board, as you can really keep track of your fuel management. Once calibrated, it is accurate, and measures fuel burn in 1/100ths of a gallon. The only apparent drawback I have found is that the Compucruise, even with the display turned off, will drain a 12 volt 25 amp hour battery in less than two weeks. This is no problem as long as you use the airplane at least once a week. But I would recommend a master switch to shut the Compucruise down completely if you don't intend flying for extended periods. This of course drops out the memory and your fuel flow calibration, but it is not difficult to reenter.

We have entered our Long-EZ in the Cafe 400 race, and are looking forward to it. We expect to be quite competitive, with the race being extended to about 400 miles from 240, and a requirement to climb from sea level to 10,400 feet and back. What with the Long-EZ's high aspect ratio and low induced drag, we should make a good showing.

Sally recently had a "#99's" meeting at the Bullhead City Airport, on the banks of the Colorado. This is a nice little cross country of about 190 nautical miles each way. We gassed up both the Long-EZ and the VariViggen. Son Keith went in the back of the Long with Sally and I flew solo in the Viggen. A beautiful day, with a 26 knot tail wind took us there at 7,500 feet indicating 120 knots with an average ground speed of 162 knots (187 mph). The return trip against a 26 knot head wind found us flying low, from 100 feet to 500 feet AGL. Crossing the desert at low altitude at 140 knots indicated is really fun, but in the Viggen it really burns up a lot of fuel. Which meant we had to land at Barstow-Dagget for gas. A quick low altitude dash from Barstow to Mojave and I tallied up the fuel burned in each airplane for comparison. While the Viggen with its 180 hp Lycoming, used 24.7 gallons, the Long with its 118 Lycoming, used exactly 12 gallons and carried two people. This is a good comparison showing the difference between a low aspect ratio (requiring lots of horsepower) VariViggen and a high aspect ratio, low induced drag (requiring very little horsepower) Long-EZ, both flying at the same speed and altitude, the Viggen averaged 8.8 gph, while the Long averaged 4.4 gph.

EZ-CALC?? FUEL FLOW INDICATORS

The EZ-Calc system as discussed in several previous newsletters, has apparently been dropped and will not be available. A lot of builders have seen the Zemco Compucruise, an automotive driving computer, in the prototype Long-EZ and as a result, several VariEzes and Long-EZs have these installed. RAF has never come out and recommended this installation however, since we were and still are very concerned with the fuel flow transducer that comes with the Compucruise. This transducer has a tiny passage way for the fuel, and it would take only a minute piece of foam or other contaminate to shut off ALL fuel to the engine. This is not at all acceptable and any EZ pilot currently using

this set up should ground his airplane until it has been changed. Also, the pressure drop is too great for a gravity system.

Byron McKean of Seguin, Texas, has done a lot of development work with the Compucruise and he has come up with a system that works great. I have one in my Long-EZ (N26MS) and am very satisfied with it. What it consists of is the basic Zemco Compucruise computer, but the transducer is discarded and an aircraft-type flow transducer, made by Flo-Scan, Seattle, Washington is substituted. Byron has also devised a neat little gadget he calls a 'Gizmo', that you can readily build yourself with parts from Radio Shack. This enables you to dial in your ground speed, and then you can get all of the functions out of the Compucruise. In effect this gives you a poor mans DME, with accurate fuel management information. I installed mine in my Long, in two pieces. I literally cut the Compucruise in half and remote wired it so that the keyboard is flush mounted into the right console just aft of the stick, and the display is mounted up at the top of my instrument panel. This was not difficult to do and it looks and works great. I have continuous information regarding fuel flow, in GPH, as well as fuel used and fuel remaining. I also have battery condition (voltmeter), inside and outside air temperature, a count up timer, and trip timer, and with ground speed and trip distance 'inputted', time to arrival, time to fuel exhaustion, etc. etc. On top of that it has an accurate digital clock. I am delighted with mine and would recommend anyone who is interested in a fuel flow indicator to go with this system.

Contact: Byron McKean
Rt 1, Box 429-B
McQueeney, TX 78123
(512)557-6575

For $12.00 Byron will send you a very complete letter with wiring diagrams, sources for parts, part numbers, prices, literally everything you need to know to do the installation. We must stipulate that we recommend this installation ONLY if you use the Flo-Scan fuel transducer. Do not use the Compucruise transducer.

SUN 'N FUN FLYIN 1982

Irene and George Rutan (Burt's Mom and Dad) again made the trip east and did an excellent job representing RAF. Irene managed again to get all the EZ pilots names and aircraft numbers. Everyone who went to Sun 'N Fun agreed that it was one of the nicest airshows ever.

RAF type airplanes were very well represented, and by the end of the week, Irene had logged in 28 VariEzes and 5 Long-EZs. She reported that they had a ball, chatted with all the pilots, and also managed a ride in the Dragonfly!!

Dick and Jeana flew out in their Long-EZ (modified) and Dick did a super job of putting on evening airshows.

The now traditional race that Dick started three years ago, was held again. Steve Woods did the officiating and 8 airplanes entered. It is

interesting to note that a standard 0-235 powered Long-EZ won, after handicap correction. He was only 7.4 slower than the fastest VariEze.

We would like to thank all the people that did such good work for RAF. Johnny Murphy, who put on a excellent forum, Dick and Jeana for helping Johnny and Dick for his airshows. Steve Woods for organizing the race, and, of course, our special lady, Mom Rutan for her tireless work on the flight line.

RAF Aircraft at the 1982 Sun 'N Fun Flyin.

Results Of The 1982 Sun 'N Fun Race

1.	Paul Mason	186.4 mph	0-235 Lycoming	VariEze
2.	Herb Sanders	184.4 mph	0-320 Lycoming	Long-EZ
3.	Jack Fehling	182.4 mph	0-200 Continental	VariEze
4.	Bruce Evans	181.0 mph	0-200 Continental	VariEze
5.	Neil Hunter	179.0 mph	0-235 Lycoming	Long-EZ
6.	Bob Woodall	169.6 mph	0-200 Continental	VariEze
7.	Rick Himerick	168.0 mph	0-200 Continental	VariEze

8. Don Riley 152.0 mph 0-200 Continental VariEze

Handicap Results
(Planes were handicapped for engine size, wheel pants, etc.)

1. Neil Hunter 184.0
2. Jack Fehling 179.4
3. Bruce Evans 178.0
4. Paul Mason 176.4
5. Herb Sanders 170.4
6. Bob Woodall 169.8
7. Rick Himerick 168.0
8. Don Riley 152.0

VARIEZE HOSPITALITY CLUB
Seven VariEzes, Kappermans, Hamlins, Wilsons, Days, Moores, Lees, and the McFersons got together at Imperial in Southern California, they then flew south across the Mexican border to Mexicali, where they cleared customs with no problems, filed flight plans, ($4.00 each) and flew en mass down the east coast of the Baja peninsula to Loreto. Four fantastic days were enjoyed by all. One day they all flew on south around the tip (Cabo San Lucas) and up the west coast to the whale breeding area, then turned east, stopping at La Paz, and then back to Loreto. The only incident was Alan McFerson blowing a main tire, no problem though, Ron Kapperman had a spare! The flight north to Mexicali was smooth and uneventful. From Mexicali to Calexico (to clear U.S. customs) had 5 VariEzes on final, when someone at Calexico suddenly noticed them and came on the unicom frequency "caution Calexico traffic, bunches of VariEzes in the pattern, they're thicker than flies!". A great trip with perfect weather, as Ron Kapperman put it, "It could not have been any better".

EZE FLY-DRIVE-IN GET TOGETHER
April 24th 10:00 am to 4"00 pm.
Place - Brookenridge Air park. (Southwest of Chicago),
960 86th Street, Downers Grove, IL 60516.
21 DME miles out on 050 radial Joliet VOR.
27 DME miles out on 305 radial Chicago Hts VOR.
West end of runway 9-27, 2800 feet, MONITOR 122.9.

Activities - Weather permitting - Picnic or hanger flying. Hosts will provide soda, bratwurst, buns for $1.50 per person to cover costs. Bring pictures, parts, anything of interest. PLEASE tell us if you are coming. 312-985-6671. Bring a salad or desert if possible.

Note - This is a private strip that is sensitive to the concerns of non-aviation neighbors so please use standard left hand pattern at 1500 msl. NO buzzing or touch and goes. No fuel. Our parking is limited, lets' limit the fly in to EZ's only if possible.

Bring any ideas for other activities in the future, bring family.
Hosts - Talbors, Steichens and Gutches.

CLUBS
A Long-EZ club has been formed in the Chino, CA area. With 26 members already, this is a fast growing club. For more information contact: Dick Kreidel

4422 Acorn Street
Yorba Linda, CA 92686

SAFE-T-POXY REACTIONS
In CP 31, we asked for reports from anyone who has experienced a reaction while using the SAFE-T-POXY. To date (April 4) we have received 47 letters, all of which have been sent onto Applied Plastics, the manufacturer.

It is still difficult for us to access the extent of the epoxy sensitization. Less than 3% of the builders sent reports of problems, but we must assume that many of you did not bother to write. Applied Plastics are presently reviewing your reports and investigating the problem. They recently sent in a random SAFE-T-POXY sample for testing and it again came back a zero on the SPI scale from zero through 10. For perspective, a common industrial epoxy. 815 has an SPI 6, while RAE epoxy has an SPI 3. SAFE-T-POXY is an SPI 0.

Applied Plastics is developing a very through pamphlet covering the use of SAFE-T-POXY and precautions to take to avoid the reaction in the first place. They also have suggestions to help you get around the problem. If you are having a slight reaction and are using SAFE-T-POXY, be absolutely certain that you do NOT have MEK or acetone or lacquer thinner in the shop at all. Just breathing the fumes of these solvents can render you vulnerable to the epoxy. Getting these solvents on your skin is asking for trouble. If you are using gloves (NEVER use Ply 9 and gloves together, it is either gloves or Ply 9) try using different types of gloves, even surgeons have allergic reactions to some gloves. Try using thin cotton liners under your gloves, this soaks up sweat, and will show you if you get a break or tear in the glove. While sweating you can sometimes be more vulnerable to allergies. A method that has worked well for some builders is to use only Ply 9, and to stop at least every two hours, wash your hands and arms thoroughly with a good borax soap (Lava) paying particular attention to scrubbing under finger nails and around your cuticles. Dry your hands, reapply Ply 9 and return to the layup. Do not exceed the two hour period. Wash up as often as necessary during a long layup. If your sensitivity to breathing the fumes is severe, full-face respirator can provide a solution. (W. W. Grainger #5X803 is an example).

To summarize, cleanliness is the 'biggy'. Do not allow epoxy, solvents or any industrial type materials, to come in contact with your skin, not ever. Wash thoroughly, often. Use a good respirator and/or ensure that you have adequate ventilation. If you still have problems you might consider switching to the RAE epoxy system. This may sound silly, (an SPI 0 to an SPI 3), but the fact is you may be reacting to a particular chemical in SAFE-T-POXY, that may not be in the RAE system. This has worked for several builders. The allergic reaction healed and they were not bothered again. Beware though, RAE is definitely more toxic. Take all possible precautions when using either of these systems. Finally, if you still have problems, let us know so that we can keep giving the manufacturer this data. Plastics good feed back.

LYCOMING 0-235 ENGINE INSTALLATION
If you bought a new engine from Avco Lycoming and specified it for a Long-EZ, your engine should be set up correctly for an oil cooler and a standard oil screen housing, not a full flow oil filter, which will not fit.

Those builders who purchase a used engine should check the following items: If you have a full flow spin on oil filter, it must be removed, so must the AC adapter that is bolted to the accessory case. There is a thin aluminum plate between the AC adapter and the accessory case, this must also be removed.

Now you need to purchase a standard oil pressure screen housing, Lycoming Part #68974, and oil screen, Lycoming Part #62817, and a gasket for the screen housing, Lycoming Part #61173.

The assembly should be bolted to the accessory case, and your oil temperature probe installed in the tapped hole in the aft end of the screen housing. If you install an oil cooler, you will also need to purchase a spring, Lycoming Part #69436, a plunger, Lycoming Part #62415, and a gasket Lycoming Part #STD-294. The plunger and spring should be installed under the large plug screwed into the top left of the accessory case. Not all accessory housings have this port. However if housing is machined for cooler it is provided. The plunger and spring are required if you have a standard oil screen and housing and an oil cooler. The plunger regulates oil to the cooler (oil cooler bypass).

There is another option available and it is an oil screen housing with a thermal valve assembly port built into it, together with a tapped hole for your oil temperature probe. This housing is Lycoming Part #69510, screen is Lycoming Part #62817, and thermal valve assembly is Lycoming Part # 75944.

If you choose to use this screen and housing you must not install the plunger and spring (#62415 and #69436). This is a situation with either one system, or the other, never both. If you choose not to install an oil cooler, you need only to install the standard oil screen and housing (#62817 and #68974). You should install the plunger and spring, or the thermal valve assembly and housing. However, your oil temperature will run hot, close to or at the red line, which means excessive wear in your engine.

0-235 L2C Engines From Cessnas 152s These engines do not have provision for a mechanical fuel pump. The fuel pump is mandatory for a Long-EZ, so you either have to get your accessory case machined (Avco Lycoming will do it and so will Air Engines, Florida) or buy an accessory case from any 0-235 that is already machined. Be careful about using an accessory case off an 0-320 or 0-360. While these parts will bolt on perfectly, they may not have the correct oil ways machined into them to lubricate the idler shafts. Again Air Engines, Florida can do this for you. You will also require a timing gear with the cam lobe on it and a pushrod.

BENDIX MAGNETOS IN A LONG-EZ?
This question comes up more and more in spite of the subject being covered in Section IIL, Page 3. The fact is that we tried to install

Bendix mags on a Long-EZ and there was an interference between the left mag (right of airplane) and the aluminum extruded angle on the right side. This interference occurs right in the area required for timing adjustment, so we called out only Slick mags. Slick mags are smaller and much lighter and in our opinion and experience every bit as reliable, particularly the newer rebuildable Slicks. We do admit though that we never really researched into the problem, possibly there might be a relatively simple fix that would allow the use of the Bendix mags, anyone who has seriously addressed and solved this problem should let us know. We do not want to get into any changes to the engine, adapter plates etc., since engine reliability is of paramount importance, and we can not recommend a change that may hurt reliability.

CP32, Page 4

CAUTION
Spinner/prop extension compatibility. This is a real gotcha! We installed a new prop extension on N79RA, which was not manufactured by Brock. We then installed a Brock spinner on this extension. The center hole in the spinner backplate was a close fit on the center locator on the prop extension. Unlike a Brock prop extension, this one had a rather large radius machined at the flange face, which did not allow the spinner backplate to slide all the way on, see sketch below.
SKETCH OMITTED

This is a dangerous situation, and difficult to detect because the flow guide prevents a visual inspection. We installed the prop, torqued the bolts to the 18-20 ft/lbs. we normally use, and tracked the prop tips accurately. At this point, the prop bolts were tight, the prop ran true, but the prop was not being squeezed against the prop extension. Rather it was pressing only against the spinner back plate, in this cas a very stiff 1/8" thick backplate, that was able to support the torque value of the bolts, without going back against the prop extension.

We flew the airplane for several hours, blissfully unaware of the problem. Last week Dick used N79RA to take a business associate to the Santa Monica Airport. On his was back he got to within 20 miles of Mojave when a strong vibration became apparent. It steadily worsened, to the point that he elected to turn back to the closest airport at Rosamond. The vibration became much worse and then abruptly went away. Dick thought he had thrown a rod, set himself up for an emergency, dead stick landing on the 2300 foot, Rosamond runway. Dick touched down on the numbers, made the turn off and rolled into an empty tie down. Not until he got out did he realize he had lost the prop and spinner.

Looking at the marks on the drive lugs it is plain to see what happened. The 1/8" aluminum back plate gradually gave way, allowing the bolt tension to relax. Without this friction between the crush plate and prop extension flange to drive the prop, it begins to be driven by the drive lugs and prop bolts in shear. This state of affairs can only continue for a very short space of time, before the bolts fatigue and then of course, the prop/spinner comes off.

This is a very serious situation and anyone who has a Brock Spinner mounted on a prop extension that is made by someone other the Brock

(obviously the Brock extension is completely compatible with a Brock spinner) should immediately ground their airplane and check this out. The problem can be cured by decreasing the radius in the prop extension, or increasing the diameter of the hole in the center of the spinner back plate.

CAUTION
When installing your engine mount, we tell you to set the mount on the extrusions leaving approximately .030 gap between the mount and the firewall, see Section IIL ,page 7. This is true if the mount is perfectly straight, however you should check to see that it is, by measuring from the firewall to the aft of the engine mount and verifying that the mount is at the correct fuselage station as shown in Section IIL, page 14 for conical mounts and page 15 for dynafocal mounts. Bear in mind that even though the mount is accurately welded up on a fixture, when it is normalized by heat treating, it is possible for the weldment to warp, creep or otherwise move enough that if you rely on the .030 measurement, you may have an engine that is not correctly located. Correctly installed, your engine crankshaft should be aligned with the zero buttline, plan view. Side view, the crankshaft should have 2 degrees of down thrust, (+ 1 degree) that is to say the spinner end is higher than the accessory case end.

CAUTION - ROTATION SPEED
Several things influence rotation speed, and thus take-off distance. The fuselage station of the axle centerline is very important. You should hold this within 1/2". (See Chapter 9 and the back cover of Section I). Toe-in of your mains also has a powerful influence on rotation speed (not to mention tire wear!). Accept nothing less than a total of 1/4 of a degree to 1/2 a degree. (N26MS has 1/4 degree toe-in, and still has the original tires, with over 700 landings, 320 hours in one year). If your tires are showing excessive wear, do not accept it, remove the axles and shim them until the toe-in is correct. This can be done quite easily by laying up one or two plies of BID on the strut and bolting the axles back on, gently tightening the bolts until the correct toe-in is achieved (by crushing the BID layup into a taper). Allow the layup to cure, then torque the axle bolts to their proper value of 75 inch/lbs. ft./lbs.). You could also use a commercially available taper shim. Aircraft Spruce sells them in various taper values.

Tire pressure can also influence take-off roll distance/rotation speed (as well as tire wear). Check your tire pressures regularly.

Ground attitude of the airplane can also cause long take-off rolls. Your Long-EZ or VariEze should sit level to slightly nose up on level ground, when loaded to gross weight. If your airplane has a pronounced nose down ground attitude under the above conditions, it should be corrected. Note that a nose-down attitude during construction is normal, before the weight of the engine and wings are added.

CAUTION CP is the latest and best information. We still have questions on this subject. If we put information in the Canard Pusher, it supercedes the information in the plans, and is the correct information to use.

CAUTION - Left Magneto Confusion

This is a problem that could lead to a serious injury. We at RAF have always considered the left and right mags to be as called out by the engine manufacturer. Even though this puts the left mag on the right side of a pusher aircraft, it is still correct to wire your mags and mag switches according to the engine manual. If you wire your EZ switches reversed from the above, obviously you will not have problems, but should you ever sell your EZ, or lend it to another pilot, he or she could get hurt if they tried to start it on the wrong mag (without the impulse) this is particularly true with Lycomings, most Continentals have both mags with an impulse. The impulse allows the spark timing to be at top dead center for easy starting, then advances for normal running. If a pilot attempted to hand prop his engine with the timing set at 25 degrees before top dead center, which is what he would have if he had the right mag switch hot, instead of the left, on a Lycoming powered EZ for example, he is likely to have the engine backfire and injure his hand. It is for this reason the Lycomings and some Continentals are always started on the left mag. If your engine had a tendency to backfire check to see that you have the correct mag grounded.

CAUTION
Carb heat on Continental 0-200 installation. If you have a Continental 0-200 in your EZ, you should test the carb heat for effectiveness. This can be done by slipping a thermometer into a small hole in the hose that connects the carb heat valve with the carburetor. This takes two people, a pilot to sit at the controls and hold the brake while he pushes the throttle to maximum power. The other person should stay well clear of the prop and should insert the thermometer into the induction hose and note the temperature rise after carb heat is applied. There should be a heat rise (carb heat temp. minus ambient temp.) of at least 90 degrees F. If not, you should increase the size or efficiency of your carb heat muff on the exhaust system. Lycomings are not nearly as prone to carb ice as are Continentals, but do not take chances, check your carb heater.

CAUTION - SEDIMENT IN THE RESIN OR HARDENER
Hardener - This is a result of temperature cycling and is not acceptable. Do NOT use hardener or resin that has a cloudy sediment, or solid lumps at the bottom of the container. You must not strain these lumps out, rather you must heat the material as described in CP 29-5 until it goes back into a clear solution, before attempting to use it.

CAUTION - TRAILING EDGE CLOSE OUTS
It is very important for structural integrity, that you ensure that your trailing edges of the canard, elevators, wings, ailerons, winglets and rudders meet the prescribed minimums in the plans. Do not accept delaminations in the trailing edge glass to glass area. Even the smallest delam can get moisture in it which will freeze and expand when you climb through the freezing level, and thus delaminate further and further with each occurrence until it could weaken the overall integrity. About the quality of your trailing edge glass to glass close outs - accept nothing less that perfection in this area. Always

sand smooth every lap after cure - do not leave them joggled as shown.
SKETCHES OMITTED

LAP DIMENSION Ignoring the proper procedure here could result in serious consequences, even structural failures! Here is a list of these areas. The minimum dimension should be considered an absolute minimum. If you don't meet this criterion it requires repair before you fly.

	Glass Lap Dimension Shown	Minimum Acceptable Lap
Canard	0.45"	0.3"
Elevators	0.25"	0.2"
Wings	0.6"	0.5"
Aileron cut outs	1.0" (top)	0.75" (top)
	0.75" (bottom)	0.52" (bottom)
Ailerons	0.5"	0.3"
Wing Root Rib	0.6"	0.4"
Winglets	0.6"	0.4"

SKETCHES OMITTED

CAUTION: Nose Gear Pivot
Correctly installed, the pivot axis should be between vertical and 5 degrees from vertical with the top aft. See sketch on page 13-1, Section I. We recently saw a Long-EZ that had the pivot oriented top forward. Under these conditions, the nose wheel is susceptible to violent shimmy which will fail the fork. Never taxi or fly an EZ if the shimmy damper is not set within limits.

BUILDER HINTS
Clarification on use of various pop rivets. Anywhere on the airframe where you are installing nutplates, on hinges, access panel, use 3/32" diameter flush pop rivets, or solid aluminum rivets. When installing aileron hinges onto the ailerons, use 1/8" round head pop rivets (Avex 1601-0410, or cherry MSP 43) rudder hinges are installed into the rudder using flush pop rivets (Avex 1604-0412 or cherry MSC 43). CS2 elevator hinges are installed on the elevator using flush pop rivets (Avex 1604-04 or cherry MSC 43).

Zolatone cockpit interior paint, is now stocked by both Wicks Aircraft Supply, and Aircraft Spruce. This paint really dresses up the interior, and is easy to apply. Mike used Charcoal Gray #40-59, and applied the Zolatone directly onto the bare fiberglass. You should scuff the shiny glass interior with 40 grit sandpaper before spraying the Zolatone. Mike did not use a primer or undercoat, the Zolatone is adequate UV protection without a primer.

Jim Heir, Colorado Springs, CO sent in an excellent suggestion for maximum utilization of space. He built a storage cabinet on the wall of his garage, with a large door hinged at the bottom. He stores his rolls of UND and BID glass inside and when he needs to cut glass, he pulls down the door, which has two legs hinged on it, and it becomes his cutting table. He also marked the surface of this table with a magic marker with 45 degree and 30 degree and 90 degree lines every 6 inches. This makes it real simple to cut the necessary glass pieces,

then close and latch the door, which keeps the rolls of glass from becoming contaminated. **SKETCH OMITTED**

When installing the Task Research fuel/baggage strakes, be certain to remove all peel ply, from inside and out. There should be two plies of peel ply, about 5" wide oriented diagonally, (see Section I, page 21.-4) which will leave a slight depression once they are removed. This depression will be filled with the one ply UND strip that laps from the top of the centersection spar, diagonally forward and around the leading edge of the fuel strake. This holds true top and bottom. Do not forget to remove the two plies of peel ply. Important this one ply of UND strip must lap from the strake onto the centersection spar smoothly, without a joggle. Sand any joggle into a smooth taper before the UND strip layup. See sketch. Next page. **SKETCH OMITTED**

Centersection Spar Clarification. A few builders have been having problems understanding the sketch in Section I, page 14-2, top right. This sketch is correct, and it shows the line you should follow on the aft face of the spar box, when you cut through the CSI foam aft face. The dimension .55" at the outboard ends is correct. The spar cap at this point is only .150" thick (top cap) and .113" thick (bottom cap). This is because the spar box top tapers to match the wing root airfoil. If you look at page 14-9, Section C-C you can see the original outside shape of the spar box shown as a dashed line. If you measure down the aft face (CSI) top aft corner to the foam under the shearweb, layup #5, you will see that it is .55". Note how the spar cap templates (page AII) set this taper. The template outside edges are level waterlines. **SKETCH OMITTED**

PLANS CHANGES

We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.

DES Desired - strongly recommended but not requiring grounding of the aircraft.

OPT Optional - does not effect flight safety.

OBS Obsoleted by a later change.

MEO Minor error or omission.

LONG-EZ PLANS CHANGES

LPC #95 DES, Section I, page 16-2, step 3, paragraph 1, last sentence. Pivot hole drilled to 23/64" (0.359). This results in an extremely tight interference fit,(0.016) and it would work better using a letter "U" drill (0.368) & better yet if you then ran a 3/8" press fit reamer (approximately 0.373) through the hole.

LPC #96 MEO, Section I, page 21-5, drawing at lower left.
Material for fuel valve mounting bracket should be 0.062 2024-T3 aluminum. The fuel valve handle should be trimmed down to clear the instrument panel.

LPC #97 MEO, Page A-14, lower winglet, tip template.
The arrow pointing inboard is correct, the words, "this side for lt.....", etc. are reversed. The side shown is for the right winglet, transfer numbers to the other side for left.

LPC #98 OBS, Section I, page 22-6, center drawing.
Delete "yaw trim bracket".

LPC #99 DES, Section I, pages 14-10 & 14-11, Sections E-E, F-F, G-G & H-H. The UND layup #3 & #4 are incorrectly shown to lap onto the CS7 & CS8 bulkheads. The words describing this layup on page 14-2 are correct. Layup #3 & #4 are layed up onto CS2 & CS3 in Sections E-E & F-F and only onto CS1 in Sections G-G & H-H.

LPC #100 MEO, Section IIL, page 6, left side, center of page.
"you will now have 4 AN509-10R8 screws....." should be 3 AN509-10R8.

LPC #101 MEO, Section IIL, page 37.
Add to the Brock parts list - two spacers, part #SP-5. These spacers are used as stand-offs to bolt the gascolator to the firewall.

CLARIFICATION

Section IIL, page 37. Part #LL-4 is used to stand off the mixture cable clamp, and is shown as a 5/8" long stand off tube on page 16. Part #LL-3 (page 37) is used inside the AN111-4 bushings in the throttle & mixture arms, and is shown as a 1/4" x 3/16" x .25" spacer on page 17.

FOR SALE

For those who would like to purchase an orifice fitting, rather than make one (CP 31, page 5, 2nd paragraph). The orifice fitting (a 45 degree elbow) required in the oil pressure - sensor line is available from: Yingling Aircraft
P.O. Box 9248
Mid-Continental Airport
Wichita, KS 67277
(316)943-0231

Order Part #0752037-3 for $21.50 plus $2.00 for postage and handling. We recently saw an excellent little panel light (very light weight), low drain and adjustable. This light is available from: David Hoffman Products
1009 Old Mill Road
Auburn, AL 39830

For Sale - Lycoming O-235-CI, 1200 total time, zero since major. Standard crank and cylinders, oil pump. A.D. complied with. $4,500 - call 707-433-6480.

For Sale - Lycoming or Continental Engines.
Norm Bender
Box 30343 AMF
Memphis International Airport
Memphis, TN 38130
(901)794-0032

For Sale - Brand new B & T propeller, 59 x 75 for Lycoming SAE #2 flange $230. Call 916-624-2119

For Sale - VariEze propeller, Great American, 56 x 68 used for 30 minutes. $200 delivered.
Call 203-666-3560 after 5pm EST
Norm Rossignol
122 Eagle Drive,
Newington, CT 06111

Bob Hansen, Long-EZ builder/flyer (N7LZ) has developed a neat program for use on a hand held TRS-80, pocket computer. Bob's goal was to replace the Owners Manual with the computer. The pilot has only to answer the questions posed to him by the computer to get all the significant performance answers. Bob admits that there may still be a few bugs in the program, but feels that it is a big jump over starting from scratch. Bob will sell any builder/flyer a commented program listing and a magnetic tape cartridge for $5.00.
Bob Hansen
22319 Marilla Street
Chatsworth, CA 91311

Spectro-Chem, Oil Analysis, a service we mentioned in CP 30, page 3, has had a price increase. Their price is now $8.95 per kit in lots of twelve or more.
Spectro-Chem

P.O. Box 29074
Phoenix, AZ 85036

VIDEO TAPES
RAF now has available a two cassette volume that contains the original "Building The Rutan Composites" as well as "Flying Is VariEze", "Defiant" and "Go-A-Long-EZ". All four programs run for a total time of 2:41. All of the above for $99.95.

We still have the single cassette of "Building The Rutan Composites", running time is 1:36 for $59.95.

California residents should add 6% sales tax and shipping to anywhere in the U.S. and Canada is $4.00, all foreign orders, add $8.00. Both of the above are available in the European PAL system.

For Sale - Lycoming O-235 (80 octane), 600 hours total time since new. NO recent Ad's apply, removed from Piper Clipper and pickled. $1,800.00.

WANTED - Original main gear strut for VariEze.
Roger Kelm
11020 Harlan
Westminister, CO 80020
303-466-4719

Main Gear And Nose Gear Struts. Of all the parts manufactured for the VariEze and Long-EZ, the ones that have provided the most challenge for us has been the S-glass gear struts. The original manufacturer began producing them in 1976. In July '79 he discontinued production, following a series of manufacturing and marketing difficulties. At that time we were unable to locate a shop who could produce the parts at an acceptable price. A better manufacturing method was required. RAF then developed the production equipment and began producing parts. RAF's policy is to only sell plans and not parts, so in mid 1980 we turned the equipment over to Task Research after it was well proven by producing 200 shipsets. RAF continued to retail the gear so we could inspect each one for quality. Task's quality has been superb, a mold-offset problem being solved with new, expensive metal tooling. Satisfied with Task's capability, RAF now no longer retails the struts.

The main struts are $326.00 and nose struts are $58.50 contact Task directly.

TASK RESEARCH INC. has for immediate delivery:
Main gear struts,
Nose gear struts,
Fuel baggage strake kits - 16 pcs. including ribs and baffles.
Fuselage Bulkheads - side consoles & roll-over structure. SASE for info sheet.

Task still have a few reject strake pieces at the discounted prices. Go to Task to inspect.

Task Research Inc.
848 East Santa Marira,
Santa Paula, CA 93060
Order Phone # 805-525-4447

SOARING IN A LONG-EZ?
A month ago, on a Sunday, Mike was up over the Mojave Airport in N26MS. He was doing a fuel flow evaluation. It was a very windy day (50 knots at the airport) but clear. During the course of the test the right tank was deliberately run out of fuel, to the point that the engine quit completely prop stopped, at which point he found himself climbing at 800 fpm! He started his elapsed timer and 42 minutes later, having gained 3,100 feet of altitude he gave up and returned to the airport. The strong lift over Mojave airport was apparently a wave condition, and had he been dressed better (warmer) he could have stayed up for much longer. He had to come down due to being very cold, not because he ran out of lift. Someday, dressed more suitably, he intends to try again.

Mike and Sally's son Keith, was involved in an accident about a year ago, which left him without the use of his legs. Keith had always wanted to fly the Long-EZ, and toward that end, Mike recently installed a temporary rudder/brake system in the rear cockpit. Keith has now flown a total of 5 hours in the front seat and is doing very well. He is hoping to go all the way through his private pilot's license in the Long-EZ. As far as we know Keith is the first paraplegic to fly a Long. Mike and Keith are working on a rudder brake system that will be hand controlled from the front seat. The Long-EZ has worked out amazingly well in this application. Keith's only prior experience was about 2 hours in a glider. He has not made a bad landing so far.

CP32, Page 8

VARIVIGGEN NEWS.
Another VariViggen first flight to report. We do not have any details or photos, but Bernard Duneman (N33VV) from Minneapolis, MN. Bernard wrote us a note saying that his first flight was on November 16, 1981 and everything went well. At this time he is progressing towards having the restrictions flown off and he expects to make Oshkosh. Congratulations Bernard!! Judging by letters received from builders/flyers, we could have four or five Viggens on the line at Oshkosh '82! Now that would be something.

N27MS continues to run well, unfortunately I don't seem to have time to fly her as much as I used to, but when I do, I am always impressed at the rapid roll rate and outstanding crosswind capability. I don't believe there is a light plane that handles better in a crosswind, at least I have not flown one. I have just done an annual inspection on the Viggen, and the only discrepancy was a crack in the aluminum carb heat box. This same problem occurred once before at about 40 hours, I rewelded it and it has held up ever since. This time I removed the offending part, which I made myself originally, so hopefully that problem will go away. Frankly I was very pleased to find so few problems. I lubricated the nose and main gear retract systems, and checked for wear, neither system required adjustment. Surprisingly I have not adjusted them since before first flight, four and a half years ago. Not flying her as often as I used to I have noticed that I

neglect tire pressure checks. This caught me out the other day when I pulled the valve out of the inner tube in the nose wheel tire. I had to replace the tube, but it shows that tire pressure must be checked. My Viggen is a little heavy at 1252 lbs. empty, so I use a little higher tire pressures than what is called for in the owners manual. For my airplane I have found 45 psi for the mains (Goodyear 500 x 5, 6 ply Flight Custom II) and 50 psi for the nose. I have been getting excellent tire life, and would recommend these pressures, particularly if your Viggen is close to my empty weight.

Incidentally, I use 100 psi in the nose strut, and I have seen virtually no loss of pressure. I have only inflated it if I have been working on it, changing fluid, etc. It has been literally flawless. Another area where I have seen degradation has been the exposed wood around the rims of each cockpit. This wood was originally painted with clear epoxy, and has been degraded by ultra violet and then moisture has got into the wood and cracked the surface. I will need to scrape it down and reseal it, perhaps with Saf-T-Poxy (low water absorption) and then I will paint it with an ultra violet barrier. Those of you who may be at this stage should give this some thought. Do not leave unpainted any epoxy or wood surface that is exposed to sunlight.

The canopy latches should be given very close attention. The plans built latches are by far the best and safest. Those of you who have seen my Viggen will know that I have had several different latch types on the airplane. For my own experience I cannot recommend what I have done. I have had my front canopy open in flight on three occasions, any of which could have resulted in an unpleasant accident. After the first two incidents, I changed my front canopy latch to a pretty fancy aircraft grade type of latch that provides a "safety" position as well as a locked and unlocked position. I was entirely satisfied with this, and felt that there was no way for it to happen again. Wrong! Circumstances can really get you in trouble. To make a long story short, I failed to lock it and for some reason the "safety" feature also failed. So I took off, hurrying to catch up to Sally, just as I was joining up with her, at only 200/300 feet, my canopy opened. I saw it out of the corner of my eye, and grabbed it with my left hand just as it reached its maximum open position. I pulled it down, moved out of formation, held the stick between my knees, and locked the canopy. My heart was going 19 to the dozen, and I consider myself lucky to have got away with it. When something like this happens, it is quite frightening, and you really feel a strong urge to panic. You must quell this, and CONTINUE TO FLY THE AIRPLANE and then lock the canopy. The reason for bringing this up again, is that I occasionally hear from people wanting to change things, including canopy latches. The best advice I can give is DON'T. Remember that we have built the airplanes per the plans and flight tested them and all of their systems. The plans built parts such as canopy latches, will work as advertised, as will fuel systems, etc. If you change any of these things, remember, when you first fly, you will be testing untried systems that may or may not work. Be prepared to take whatever action may be necessary in case you have a problem.

Speaking of problems, several builders are still using the cable driven main and nose gear systems. Based on my own as well as almost all the Viggens that have flown, I feel you are taking an unnecessary risk. ALL of the cable driven systems that I know of, have had at least one

failure. The worm/ worm gear and chain systems installed in N27MS and called out in the second edition of the VariViggen plans, has performed flawlessly, and is the only system currently recommended by RAF. We do still have plans available for the main gear retract system.

Several builders have called or written, asking if there is a VariViggen club, or if not, could one be formed. I think this is a good idea and would be happy to try to form such a group. Any builders willing to help others, show their projects or completed airplanes, talk on the phone, answer written questions, or just provide moral support, and are willing for me to provide their names, addresses and phone numbers to inquiring builders, please let me know.

FOR SALE - VariViggen project. Fiberglass parts, wing attach fittings, 500 x 5 wheels and brakes, master cylinders and brake pedals. Will trade for Long-EZ parts.
Contact. Ron Lorimor.

(916) 842-3008

Elmer Hamerick reports that he purchased a flap motor, complete with ball screw, 2 micro switches, (out of a Cessna 150) which he intends using for his reflex drive. Elmer purchased the flap motor from:

Ellington Aircraft Salvage,
30982 E Broadway,
Toledo, OH
419-666-2440

A similar flap motor is also shown in the latest Wag-Aero catalog, page 50. Part # 1-205-000

A letter from VariViggen owner, Len Dobson.
N73LD, Serial #533 was built from the first edition VariViggen plans, including the cable retract system. However, before skinning the aircraft I removed the cable system from both main and nose gear assemblies as it was far from being trouble free. About the time Mike came out with the drawings for his gear modification, I had already devised and installed a chain drive system. This system appeared to be quite reliable during ground tests so I completed the aircraft. All went well for approximately 100 landings. However, I had not anticipated the stretching of the chain with continued use. Even though I had installed idler sprockets in the system, they were apparently not enough to take up the slack in the drive chains caused by the stretching.

On December 1, 1981 while landing at Brenham, Texas in a 30/35 knot cross wind the right down lock cam MG 5, slipped out of the notch on beam MG 4, putting all the side load on MG 6 push rod and MG 5 cam.

The gear had been extended on the down-wind leg, and I had three green lights on the panel on final approach. The limit switches on my gear system are expensive aircraft type environmental micro-switches, and they

were adjusted for positive over-center down lock. The slack in the chain combined with the poor configuration of the notch in beam MG 4, (which I had purchased from a vendor), caused the cam to slip off the beam and fracture. (See drawing) I had rolled about 200 feet after touch-down right down the center line with the aircraft under full control, when a sharp gust hit the aircraft from the left. I heard something snap, and the right wing tip dropped to the runway. I was still rolling at about 60/65 mph, and I was unable to keep the aircraft on the runway because of the drag. The infield adjacent to the runway was quite soft and muddy from recent rains, and as the nose wheel dug in, the strut and nose gear assembly tore out of the side bulkheads F 12, 16, 17 and 31 between F20 and F 32. For just a brief split second it felt as though the Viggen was about to cartwheel, but it fell back as the nose gear folded, and then the left main collapsed inward. At this point the aircraft was completely flat on the bottom, and it skidded on the wet grass on its belly with mud and grass flying over the canopy for about 300 feet before coming to a stop.

Retrieval was accomplished without further damage mainly through the efforts of my good friend Dr. Norman Gabriel and Brenham, Texas who is also a Viggen builder.

I was quite surprised and pleased to see how well the airframe stood up. My only injury was a bruised right toe caused by the rudder pedal tearing out. Damage to the Viggen consisted of moderate skin damage to the belly, nose wheel well bulkheads, right brake line, right rudder pedal, entire nose gear assembly except for the wheel and fork, and the main gear retract system.

My VariViggen is flying again, but this time with the Melvill gear modification, and believe me - don't fly without it!!!! The modification was difficult to retrofit with the skin on, but not impossible - nothing comes "EZE" on the Viggen. The modifications and repairs took about three months, "Blood, Sweat and Tears" went into making it a much better ship than I had before.

New World Records Set By Long-EZ
Dick Rutan, who has set three world distance records, two in Long-EZs and one in the VariEze prototype, is at it again. This time, joined by Jeana Yeager, they have set five new speed records. World speed records are categorized by weight and by distance flown. Separate records are recognized for female pilots. The weight category is C1b, for light planes under 1,000 kg. (2,205 lbs.). Speed records are recognized at distances of 3 km., 500 km.,1,000 km. and 2,000 km. Due to the Long-EZ's capability of flying long distances at high speed Dick and Jeana attempted to break the following previous records:

Speed C1b absolute closed course.

500 km.	USA	G. Mock	Aero Com 200	1965	206.7 mph
1,000 km.	USA	H. Fishman	Waco Meteor	1969	200.4 mph
2,000 km.	CZECH	L. Stastny	Sokol CK-CLE	1956	173.7 mph

Speed C1b female closed course.

500 km.	(none set)				
1,000 km.	CZECH	V. Touzimska	Sokol L-40	1980	131.4 mph
2,000 km.	CZECH	V. Touzimska	Sokol L-40	1980	128.9 mph

To put things in perspective, the 2,000 km. speed record requires a full throttle dash at low altitude a distance equal to a trip from Los Angeles to Dallas! Dick and Jeana's non-standard Long-EZ (O-320 Lycoming and some structural mods) attains a true airspeed of 223 mph (194 kts.) when clean. This slows to 212 mph (184 kts.) when all the leading edges are clobbered with bugs (loss of laminar flow). Speed records are set by block speeds, however, resulting in losses due to wind and turns at each end of the course.

The attempts were not as easy and straight forward as one might have hoped. On Dicks first attempt, he experienced a broken aluminum fitting (remember CP 31 changes?) in the fuel system which dumped about 5 gal/hr through the engine compartment - luckily no fire, but it resulted in inadequate fuel to go the distance. Two of the record runs were done in rain showers, resulting in extensive prop damage at the 3,000 rpm condition he was running. In all the attempts, the 0-320 logged over 25 hours of time at 108% of rated power, at 11% over rated rpm, without problems. The Microlon manufacturer sponsored the attempts. The engine was treated with Microlon oil treatment. Room here does not permit the full story of the attempts - this should appear in the aviation press. Attempts in all record categories were successful, the new world records are listed below. Long-EZs now hold 7 world records!

Record	Pilot	Dist. km.	Speed mph
Absolute	Dick	500	211.51
Absolute	Dick	1,000	207.84
Absolute	Jeana	2,000	204.58
Female	Jeana	500	207.10
Female	Jeana	1,000	205.00

LONG-EZ FIRST FLIGHTS
There are now 16 Long-EZ's flying, that we know of. If you know of one not shown in CP 31 or below, please let us know his or her name, address, N-number and date of first flight.

Herb Sanders	TN	N81HM
Bryce Heffley	CO	N78AB
Paul Adrien	MA	N46AA
Sam Harris	MS	N766SP

VARIEZE FIRST FLIGHTS
Since the last report, the following VariEze's have flown. If you know of one not shown below or in a previous newsletter, please let us know his or her name, address, N-number and date of first flight.

Shirl Dickey	UT	N60SD
Dave Cherwink	MD	N78JH
Earl Ellis	OH	N547EZ
Dale Collins	IL	N224DC
George Holmes	CA	N104P
Bill Butters	MO	N235LB

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

Robert Schubiger, Switzerland. He keeps his VariEze at home, hangers are difficult to get and very expensive. Robert is an airline pilot and flies DC10s.

Rudi and Dane Kurth's VariEze, was the second EZ to fly in Europe. Rude attends many airshows all over Europe. He is seen here at Leicester Air Show in England.

G-LASS, the first VariEze to fly in England, owned by Don Foreman and the holder of several point to point world records.

F-PYHR is owned by Monsieur Briquet.

Monsieur Morelle's (F-PYHZ) and Monsieur Guimbal's (F-PYHT) also at the Leicester show.

F-PYIP, is owned and operated by the Peugeot Aero Club in France.

Monsieur Morelle taxiing out for his first flight.

PHOTOGRAPHS OMITTED. PHOTO CAPTIONS ARE GIVEN BELOW

The Grizzly, shown above in slow flight with full flaps. The Griz has been a low priority project because of other commitments, but is a lot of fun to fly, and Burt and Mike fly her every chance they get. The photo below was taken out the right 'blister' window, and shows 60 percent flaps down, the fuel gauge and fuel sump blister on the fuel tank (wing interconnect) and her shadow framed by the wings and fuel tank. Photo by Pat Storch.

Brief Long-EZ specifications/Performance

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the complete plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 larger full size drawings. It includes many photos, over 800 drawings and illustrations, and over 65,000 words. The builder is led, step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction manual for the complete engine installation including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.
SECTION IIA - Continental 0-200
SECTION IIC - Lycoming 0-235

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

LANDING BRAKE - Complete full size drawings for the landing drag device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

LONG-EZ NOW APPROVED FOR GRASS FIELDS.
Rutan Aircraft has recently tested a spring loaded "shock strut" which was installed in place of the NG9/NG10A nose gear strut on Long-EZ. This, combined with 500 x 5 tires, was tested by progressively taxiing over 1" x 2"'s, 2" x 4"'s and finally over two 2" x 4"'s, one on top of the other. The results showed a very significant increase in the rough-field absorption qualities of the landing gear. Taxiing over stacked 2" x 4"'s resulted in very acceptable loads, with a satisfactory ride.

We then flew N79RA to an average grass strip and conducted takeoffs and landings at a range of weights and cg positions. Also, taxi tests in tall grass and undulating surfaces was satisfactory. A Long-EZ with the spring strut and 500 x 5 main tires is now approved to operate from average grass fields. This does not mean it is acceptable for gravel or unprepared/rough surface. The prop damage that can result from operating on gravel is unacceptable. The spring strut will be available from a Long-EZ distributor as an option.

THE FOLLOWING ARE RAF-AUTHORIZED DISTRIBUTORS OF LONG-EZ MATERIALS AND COMPONENTS. CONTACT THE DISTRIBUTORS AT THE ADDRESSES SHOWN FOR THEIR CATALOGS AND DESCRIPTION OF ITEMS.

Back Issues	$1.50

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 33. If you are building from 2nd Edition plans you must have newsletters 18 through 33. If you are building a VariEze from 1st Edition plans you must have newsletters from 10 to 33. If you are building a VariEze from 2nd Edition plans you must have newsletters from 16 through 33. If you are building a Long-EZ you must have newsletters from 24 through 33.

A current subscription for future issues is mandatory for builders, as this the only formal means to distribute mandatory changes. Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca. approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 on Saturday. Closed Sunday.

If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to flyins. When arriving at Mojave by car turn east at the Carl's Jr. restaurant to find the airport.

When writing to RAF send a stamped, self addressed envelope along if you have any questions. If you are placing an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed up your reply.

Please note that RAF is closed during the year on the following holidays:

New Year's Day	January 1.	
Memorial Day	May 30	3 day weekend.
Independence Day	July 4	3 day weekend.
Labor Day	Sept 6	3 day weekend.
Thanksgiving	Nov 25	
Christmas Day	Dec 25	3 day weekend.

RAF will be open during Oshkosh. On the 1st and 7th of August we will run the videos and the prototype will be here. There will be no flying. Builders please note that there will be no one to answer builder questions during that two weeks.

RAF ACTIVITY
Since the last newsletter has involved flight testing of our new Solitaire self launching sailplane, development of aero tow capability with the Grizzly, competing in the 1982 Cafe (Competition in Aircraft Fuel Efficiency) race, homebuilder support, various technical lectures and presentations and several aerodynamic and structural consulting jobs.

OSHKOSH 1982
The world's largest airshow and convention, the EAA flyin at Oshkosh, Wisconsin, July 31 through August 9th should prove to be an interesting one this year as several new RAF-designed aircraft plan to make their debut: the new Solitaire sailplane, the STOL Grizzly, the Amsoil Biplane Racer, and the NASA skew wing AD-1. Demonstrations are planned by the Solitaire being towed by the Grizzly as well as Long-EZ flight demonstrations. In addition, Long-EZ's and VariEze's are expected to race in the LBF Oshkosh 500 race. The arrival of the NASA skew wing AD-1 is significant in that although the aircraft was completed in 1979, Oshkosh 1982 represents the first public showing of the AD-1 and flight demonstrations are planned. Old time readers of the Canard Pusher will recall that the AD-1 began as an unsolicited proposal by RAF to NASA in late 1975. The aircraft was designed by RAF in 1976 - 1977 and built by Ames Industrial Corp. in 1978/1979. Raf had hoped to also unveil the small twin engine jet trainer demonstrator, the Fairchild NGT. However, since source selection for the Air Force trainer competition has not yet been made, the NGT will remain at RAF awaiting the possibility of additional flight testing. FLASH - As we are going to print it has been announced that Fairchild Republic has won the Air Force trainer competition!

Discussion and technical presentations by RAF at this years Oshkosh event are listed below.

Date	Time	Place	Subject
Aug 1 Sun	3:00pm	Tent #2	Long-EZ
Aug 3 Tues	3:00pm	Tent #2	Solitaire
Aug 4 Wed	3:00pm	Tent #2	Grizzly
Aug 5 Thurs	10:30am	Tent #1	Aerodynamic Features of the Tandem Wing.

SOLITAIRE COMPLETES SELF-LAUNCHING & AERO TOW FLIGHT TESTS
The new Solitaire has exceeded its design goals on performance and has proven to have flying qualities that represent a significant improvement over currently available sailplanes. The Solitaire is the first high performance sailplane that exhibits true stall-proof flying qualities, allowing slow thermalling flight and return to airport after rope break without the high risk of stall or departure. The visibility is excellent with the canard providing pitch and roll attitude reference. The wing "spoilflaps" have proved to be very effective for flight path control and result in a very minor pitch trim change. The directional stability and tow qualities are excellent and do not result

in the tricky aero two characteristics normally found on the very small conventional sailplanes.

As shown by the accompanying graph, the static pitch stability of the aircraft is quite high, resulting in a relatively large elevator travel with speed and a minimum trimmed "full aft stick" speed of 34 knots. During powered flight the thrust trim change due to the high mounted propeller is minor due to the 4 degree propeller thrust angle. Initial testing indicated an apparent over-sensitivity during flight in turbulence and during tow plane wake transitions. This was traced to a combination of incorrect gearing in the pitch control system and excessive control system friction. Improvement of those items has resulted in satisfactory longitudinal flying qualities. Continuous flight in tow plane wake is possible without overcontrol tendencies. The initial configuration proved to have inadequate roll rate to allow rapid thermal side step maneuvering. The roll rate was similar to the larger open-class sailplanes. By the time you read this newsletter, the roll rate should have been improved by a modification to the ailerons increasing their span, deflection and chord. Directional stability and control is excellent as is the nose gear steering of the bicycle-wheel configuration. Unlike most sailplanes the Solitaire can be taxied or towed to the active runway without ground handling requirements.

The accompanying figures show the measured soaring performance of the Solitaire, conducted in still air by timing decents through 300 to 500 foot altitude bands. As shown in the comparison, the Solitaire performance lies between the 1-36 and the 15 meter 1-35 sailplanes. This is exceptional performance for its 12.5 m wing span. The minimum sink rate at sea level of 135 fpm should allow thermalling capability even in the relatively weak Midwest soaring conditions.

The development of the motorized self-launch capability is being conducted using two general power concepts. After evaluation of both has been done, one will be elected for the plans configuration. The first involves a fixed, single cylinder, two cycle, seventeen horsepower engine with carburetor and exhaust system mounted in the forward fuselage. A row of three V belts connects the engine to a retractable boom which houses the top bearing pulley, flange, and 42 inch propeller. This is the configuration that was used for the initial flight tests. Following those tests the aero tow development was conducted. The aircraft was initially towed with a Super Cub and then the Grizzly. Aero tows

---

have been satisfactorily conducted in strong gusty winds to 30 knots and crosswinds as high as 15 knots. The second propulsion concept considered involves a light weight (18 lbs), two cylinder, two cycle engine with a direct-drive propeller that is retracted on a boom. The engine, carburetor, exhaust system and propeller installation in its entirety is extended from the fuselage for self-launch. This system is undergoing ground testing and should be flying soon. We at RAF are looking forward to our entry in the Soaring Society of America's homebuilt sailplane competition to be held September 4-6 at Fantasy Haven Airport in Tehachapi, California. The goal of the competition is

to promote soaring by the availability of a low-cost homebuilt sailplane.

SOLITAIRE PERFORMANCE CHARTS OMITTED

EZ's SWEEP THE CAFE FUEL EFFICIENCY 1982 COMPETITION!
The prestigious Competition in Aircraft Fuel Efficiency race held this year at Santa Rosa, California, served as a dramatic demonstration of high efficiency and utility of RAF homebuilts. As shown in the adjacent tables and charts the EZ's swept the first four places in the two-seat experimental category. Dick's Long-EZ, carrying three people (a total of 600 lb. payload) placed first, above all other experimental aircraft. The RAF Defiant, carrying an impressive 1,200 lb. payload (six people) placed second in the Experimental category. Mooney's noted designer Roy LoPresti flying a Mooney 201 with (five seats occupied), won the production single category and edged out the Long-EZ's Cafe score by approximately 3%. Overall placings are shown in the adjacent table.

The impressive lineup of over 50 airplanes ranged from single seat Quickies to the high performance Piper Aero-Star. The planned 400 mile race course was shortened due to a thunderstorm at the third turn point which was the top of 10,560 ft. Mount Lassen. We would have expected the EZ's to score even higher had the Mount Lassen turn point been included due to the excellent high altitude efficiency of the EZ's. The race was accident free, the only incident being a tailwheel failure of a Q2 on landing and a Q2 which experienced engine failure on initial climb but landed safely.

The officials, headed by Dr. Brien Seeley, should be commended for the through and professional way in which the competition was run. The enormous job of handling the weighing, impounding, timing, and payload determination of that large a group of dissimilar aircraft is no minor task. The weighings this year were accurately measured and averaged by sophisticated equipment. Thus, the suspected inaccuracies of last year that may have distorted some of the results (particularly on the lighter aircraft) probably did not occur. The CAFE score this year was computed as CAFE = MPG x MPH x payload. Last year's equation was CAFE = MPG x MPH x the square root of payload. We calculated scores using last year's formula and this year's data to assess the results that would have occurred if the 1981 formula had been used. The adjacent table shows that the result would have Gary Hertzler's VariEze placing first overall, with this year's winner (the Mooney) placing sixth.

In order to visualize the relative efficiency, a graph of miles-per-gallon versus miles-per-hour is shown for two and three place experimentals. **GRAPH OMITTED** Note that the Long-EZ's performance was close to the handbook data for continuous cruise (at the 3,000 ft. average race altitude) even though the CAFE course required extra fuel and time for takeoff, climb and winds aloft. The two-seat experimental winner, Gary Hertzler, flew an A-80 Continental powered VariEze. He prepared for the face by gathering extensive fuel flow data and conducting a technical computer analysis to optimize his speed and climb/descent strategy. Gary capped off a successful race weekend with a spectacular non-stop flight back to his home in Phoenix.

In developing a formula to assess aircraft efficiency, the question always arises of how much importance to place on speed. The CAFE 1981 and 1982 formulae place equal importance on miles-per-gallon and miles-per-hour by multiplying their values together. A solution to the question of speed's degree of importance has been proposed by Don Crawford and, as a result, "Honorable Mention" prizes were awarded this year based on his analyses. The winners were determined by constructing "first echelon" and "second echelon" surveys of efficiency, in which equal award is given to the best

---

slower (but high mpg) aircraft and the best faster (but lower mpg) aircraft. The first echelon represents a group of first place winners and the second echelon represents a group of second place winners. The Crawford "first echelon" went to the VariEze, Mooney 201, Defiant and Bonanza. The "second echelon" prizes went to the Long-EZ, Twin Comanche and Glasair.

In general, twin-engine aircraft are less efficient than single engine aircraft, thus the CAFE prizes are separated to group the twin-engine aircraft together and allow them to compete against each other. Their places and scores are shown in the adjacent table. It is interesting to note that even though the RAF Defiant is a twin engine aircraft it was surpassed only by the Mooney 201 and Long-EZ in the overall CAFE scores.

Each year as we participate in the CAFE efficiency contest we learn new and better ways to improve aircraft performance..This year Peter Garrison, the Flying magazine writer who entered his long-range Melmoth, had prepared a complete computer program to analyze the entire race course and to assess the effects of different climb and descent strategies. We expect the refinements done for this prestigious competition may result in the improvement of general aviation efficiencies. We would not be surprised if someone was able to score in excess of 3 million during the next CAFE competition.

WATSONVILLE 1982
Sally and I flew N26MS into the Watsonville Flyin on Saturday May 30. The coast was socked in with typical low clouds, but we found a hole south of Salinas, and were pleasantly surprised to find ourselves alone in the pattern. Previous years, the Watsonville pattern has been much like Oshkosh first day. There were a lot of airplanes already parked on the flight line. After parking with the VariEzes, we counted 23 VariEzes and 2 Long-EZs on the line. We then nearly ate ourselves silly with giant sized strawberries and artichoke hearts while watching

a super airshow, a real Jenny doing loops, spins, etc. was unforgettable. Unfortunately, we had to be back that evening so we had to leave right after the airshow. We had a good tailwind and got back to our home base of Tehachapi (exactly 200 nm or 230 sm) in one hour flat!

Ams/Oil Rutan Racer
Dan Mortensen of Duluth recently broke the world speed record in the C-1-B Class for the National Aeronautics Association 3 kilometer course. He flew the Ams/Oil Rutan, a racing biplane owned by Ams/Oil. Mortensen recorded an average speed of 234.62 mph, breaking the old record of 227.24 mph set 16 years ago. At the 1982 Sun "N Fun EAA flyin in Lakeland, Florida, the Ams/Oil Racer won prominence of its own by being named the "Best Original Design".

Neal Johnson, Long-EZ builder #986, has worked up an excellent plans change/builder hints summary, itemized in Chapter order. It is well presented and covers CP 24 through CP 32. Neal plans to update this summary as required. This should prove to be a very handy aid to anyone building the Long-EZ. Contact:
Neal Johnson
P.O.Box 51
Monroe, LA 71201
Price is $7.50 to cover cost of postage.

VARIEZE HOSPITALITY FLYIN
Taos, New Mexico. What can you say about such a magnificent place? Twenty two VariEze's, two Long-EZ's and one VariViggen flew in to Taos, New Mexico on July 2nd and 3rd, with a total of 56 people. The weather was beautiful, cooler than usual. Charles and Joan Richey did a super job of organizing food, river trips, hiking and making everyone feel relaxed. By noon Saturday the whole crew had arrived and the "stories" started over lunch at the airport. How about one body being overheard on the radio asking "how do I run this gizmo, which button do I push now?" also a group, which shall remain nameless, getting lost and making a detour into Colorado!!! Up to the Condos to relax those tired flying muscles in the jacuzzi with beer, wine or Koolaid. The Condos are at 9,300 feet amongst the most beautiful pine and aspen trees with a stream running right by the front door. Steaks cooked on the barbecue came next, and more tall tales.

On Sunday, some folks slept in, others went on the river trip, some into town. Charlie, the gentleman who runs the condos, took the rest of us up the mountain to 11,500 feet in his four wheeler. You go up 2,200 feet in two and a half miles. We walked up to 12,000 feet to the most spectacular view ever, with wild flowers everywhere. We then braved it and walked down the mountain. More jacuzzi and supper in town. Monday morning saw everyone leaving and really wanting to stay. Thank you Charles and Joan Richey for making possible such a super weekend.

The following people drove or flew in:

Michael and I disagree on the number of VariEzes that are listed. He says that I have left someone off, but he is not sure who! Let me know if I have.

IVHC OSHKOSH BANQUET
Don't forget, this year the banquet will be held on Sunday, August 1st at 7:00 pm for cocktails and 8:00 pm for dinner. It will be held at Butch's Anchor Inn. Pay at the door. This banquet is open to anyone flying an EZ or members of the IVHC.

VariEze Help
William Rice is willing to show his VariEze and even give a back seat ride to any EZ builders in the northern California area. Bill has over 300 hours on N103B. Contact: Bill Rice, 1156 Ridgewood Drive, Eureka, CA 95501

A First Flight By Charlie Gray Of Florida
"Here I am at 35,000 ft. dead heading home from Boston to Miami on June 6th, 1982. Exactly 1 year 3 months after two kits arrived at my workshop, triple 5 Long-EZ made its first flight I cannot describe the sensation, in word form, as I pulled back on the stick and was airborne for the first time. It's just terrific - there were no trim changes required, it just flew and flew great. After once around the pattern and a smooth landing I taxied back for a kiss from my wife and hand shake from friends, I took off again for the second flight, this time for about one hour.

I was able to test low speed (59 mph) stall or nod and high speed about 170 mph at 1,500 ft. 87 degrees, 2850 rpm, for a true of about 177 mph. No spinner and pants. That's with 108 hp, 0-235-C2 engine and 25 lbs. in nose for center of first flight cg box. I even found some rain to fly through with no problem except small nose down pitch change. About 500 fpm, easy trim out.

It seems so inadequate to just say thanks - the superb plans, followed by CP newsletters and unbelievable builder support. The job being done by RAF is second to none in the home builder industry. It has been a joy to work on this project and I join with you all at RAF as a member of a very proud group of EZ flyers. We are looking forward to many happy hours of flying.
So Much Thanks,
Charlie Gray".

PLANS CHANGES
We at RAF, of course, cannot enforce a mandatory change, as FAA can on a type-certified aircraft. The regulations allowing amateur-built experimental aircraft recognize that the homebuilder is the aircraft manufacturer and, that the aircraft does not need to conform to certification giving him the freedom to develop new ideas. FAA achieves their goal of providing adequate public safety by restricting the homebuilder to unpopulated areas and to solo flight until his aircraft is proven safe.

It is the homebuilder's responsibility to maintain, inspect and modify his aircraft as he desires. However, we at RAF feel that part of our job is to provide information to the homebuilder in the form of recommendations that, in our opinion, are required for him to achieve a satisfactory level of flight safety.

Category	Definition
MAN-GRD	Mandatory, ground the aircraft. Do not fly until the change has been accomplished.
MAN-XXHR	Mandatory, accomplish the change at next convenient maintenance interval or within XX flight hours whichever comes first.
DES	Desired - strongly recommended but not requiring grounding of the aircraft.
OPT	Optional - does not effect flight safety.
OBS	Obsoleted by a later change.
MEO	Minor error or omission.

LPC #102 MEO, Section I, page 21-4, step 6.
Strike the 5th, 6th and 7th sentences. Substitute the following: "Glass the inside with one ply of BID. Flox in place holding with nails. (Section F-F)".
Page 21-4, step 7. After "halfway down O.D.", insert "lapping 1" onto the forward face of the centersection spar".

VariEze and Long-EZ MEO
Owners Manual appendix three add "CAUTION friction in the pitch system can seriously degrade flying qualities". Also add ditching procedure shown on next page.

CP33, Page 4

EMERGENCY PROCEDURES
Ditching in water

Actual ditching has not been experienced to test the following procedure. However, this should provide the best chance for success. Wear your life jacket for overwater flying. On descent, bend safety catch away but do not open canopy. Extend the nose gear. Touchdown should be planned at minimum speed, landing into the wind. Land on the back side of a swell, or parallel to the swells. The aircraft or major components of the airframe should float and support occupants and equipment due to the large amounts of structural closed cell foam.

CAUTION! CONTROL SYSTEM FRICTION
The presence of friction in the pitch controls of an EZ will result in serious degradation in flying qualities. Mike recently installed a different shape canard tip and when reinstalling the elevators one of the pivot bolts was adjusted to bind an elevator. Sally and Mike both flew the aircraft with friction and reported PIO tendencies and over-control difficulty. Adjusting out the bind immediately returned the excellent pitch control and smooth flying qualities.

ACCIDENT - Inflight Airframe Failure
The thought of an airplane coming apart in the air brings chill to most aviators and certainly to aircraft designers. Despite many horror stories related to severe weather, drastic overspeed in dives, and even airframe flutter (unbalanced elevators), we had yet to hear of an inflight failure of a Rutan design - until June 21st when the caller described a winglet ripping off a VariEze at 200+ mph during an airport buzz job. Within two hours Mike Melvill and Dick Rutan were airborne in the Defiant for a non-stop flight to Dallas, Texas to investigate. What they found, though, did not lead to grounding or flight restriction of other VariEzes. The cause was tantamount to leaving the wing attach bolts off your Cessna and expecting the fairing strip to hold the wing on. Their report follows:

An aerobatic pilot witness standing nearby described what happened when the winglet came off. The aircraft yawed, rolled, and pitched up 90 degrees. The calculated 13-g loads did not fail the wings but twisted the fuselage enough to shed most of the plexiglass from the canopy frame. The aircraft impacted inverted on the prop and top cowling, then it slammed down, shearing the pilot's rollover structure, the top of the instrument panel and impacted the canard/fuselage fairing. It then bounced back into the air, rolled left to upright, and struck the ground upright,failing the main gear (pulled brackets and major glass structure from the fuselage). The aircraft came to rest 90 feet from the initial impact point at a heading of 110 degrees right of flight path. The nose gear was retracted. The right winglet was located

about 1,900 feet short of the wreckage. Parts of the plexiglass canopy were found 1,000 feet short. With the exception of the right winglet and rudder assembly, and parts of the plexiglass canopy, the wreckage was essentially complete and in one spot. Although it had sustained major damage, the airplane was located in a small area, not over 20' x 30'.

The right winglet failed inward during the high speed low pass. Sample sections were cut out of the winglet-root/wingtip. Skin coupons were burned out and the number of plies were counted. The type of glass and fiber orientation were determined.

Figure 1 shows the VariEze design structure and the structure found on the wreckage of N11CH. The major tension layup (#8) that was omitted was, without question, the primary weakness which allowed the winglet to fold inward and fail at high speed. The winglets lift inward and, at high speed (with zero sideslip) have an inward bending moment that is equal to that attained in a 15 degree sideslip at the maneuvering speed. Note that with layup #8 omitted, and with layup #9 not extending to the lower skin, the only structure opposing the bending was the foam core acting through rib #6 to the bottom skin. It is conservatively estimated that the structural strength of the winglet-to-wing joint of N11CH was less that 1/20 of what it should have been. It is very surprising that it did not fail sooner. The incredible thing that was not answered was how the builder could have omitted the primary structure and why it had not been noticed. Even after the final paint job, it was obvious that the #6 rib could be seen on the surface.

This aircraft throughout showed evidence of poor workmanship. Poor workmanship in itself had not precipitated structural failure with these construction materials. Prior to this accident the VariEze type had amassed approximately 150,000 hours flying without inflight airframe failure, even though many of the aircraft have relatively poor workmanship. The omission of important primary structure was clearly the cause of the structural failure.

SKETCHES OMITTED

CP33, Page 5

ANOTHER PROP INCIDENT

Ray Johnson from the San Francisco Bay area, flew his VariEze to Las Vegas, where it was parked in the desert sun for 5 days. He then took off and headed south at 12,500 feet. About 20 miles north of Apple Valley airport, a horrendous vibration set in. Ray throttled back, pulled the mixture to idle cut off and pulled the nose up to slow down. When the engine stopped turning, the vibration went away. Ray glided in to a landing at Apple Valley. Other than the Cessna that pulled out in from of Ray on final, causing him to have to land off to one side of the runway, it was uneventful. Ray's prop was still on the airplane, 5 bolts had sheared, one was bent but still holding and the spinner retained the prop.

This is a classic case of flying from a moist ocean climate to a dry desert climate. The wood prop shrinks just a little bit, the bolts no

longer have the correct torque, so the prop starts to move and in literally seconds, the bolt holes and drive lug holes become elongated, and the bolts break off at the drive lug due to fatigue.

Check your prop torque, it should be between 18 ft/lbs. (216 inch/lbs) and 20 ft/lbs. (240 inch/lbs). With a new prop, you should check the torque after one flight. Then again after 10 hours, then at 25 hours, and thereafter every 25 hours.

NOSE WHEEL SHIMMY/FAILURE

We have heard of three more nose wheel fork failures. This is a part of our airplanes we seldom see; it is retracted when parked and we are usually in the seat when the gear is extended. Do not neglect to check you nose wheel during your preflight. Pay particular attention to the friction damper. You should grab the tire as far aft as possible and swing the fork left and right. It should take 2 to 4 lbs. of force to do this. If you are not certain how much 2 to 4 lbs. is, use a spring scale to calibrate yourself. If you have less than 2 lbs., it is possible for the nose wheel to shimmy. This shimmy or flutter instantly goes divergent and in only a fraction of a second the fork will fail, due to side loads. The nose wheel/fork, can bounce back and go through the prop. The nose wheel fork is designed with more than enough integrity to take the maximum expected landing loads and has been tested to over 80% above the FAR Part #23 requirement without failure (see CP #18). This type of failure caused by shimmy generally occurs with very little load on the nose wheel, usually at the very moment of a nose wheel touch down, or even at the moment of nose wheel lift off during a take off. The new shimmy damper spring called out in CP 30, page 4 MUST be installed and correctly adjusted. Also check to see you have no ovalizing or bending of the NG17 steel tube and that the thick-wall (0.125+ wall) NG17 is installed.

LONG-EZ PROPELLER UPDATE

We have been testing a few different props on the Long-EZ, and we are finding the best all round performance for the 0-235 Lycoming to be a 62" dia. x 66" pitch. This is a larger diameter than the maximum diameter called out on the back page of the plans, however, we have several hundred hours on two of these props, on N79RA and N26MS and we have not encountered any problems. These props are available with the urethane "rain proof" leading edge from the following two companies:

Ted's Custom Props	B & T Props
9917 Airport Way	8746 Ventura Avenue
Snohomish, WA 98290	Ventura, CA 93001
(206)568-6792	(805)649-2721

We have had one each of these props on test for over a year, and both perform flawlessly and are very close in performance. Be sure to get your prop order in at least three months prior to your estimated first flight date. Don't let yourself be caught with a finished airplane and no prop to fly with.

BUILDER HINTS

Terry Crow suggests an insulated box to keep your epoxy pump and epoxy warm. Build it out of styrofoam. (bead board ok). Glue it together with epoxy, make hinges out of BID, epoxy them on. Leave them dry at the hinge line. Terry keeps his at 85 degrees + or - 3 degrees with a

cheap fish tank heater in a plastic bottle filled with water. Parts cost $8.00 and one hour of time. Terry also suggests that if you have not used your pump for a week or more that you discard the first squirt, as the ratio can be off.

Christopher Brichamban suggests you try sticking a 1/4" wide strip of masking tape along the cut lines on your BID. Cut down the center of the 1/4' wide masking tape, carry it to the plane and lay it up. The masking tape comes off quite easily and this allows you to maintain the shape of the BID between the cutting table and the plane.

Dan Wicklund says a 20 gallon styrofoam ice chest (24" x 14" x 14") makes a great storage area for keeping resin, hardner etc. at 85 degrees. Use a 40 watt light bulb and a dimmer switch, run the chord through the drain hole and set the whole works on 2 scrap 2x4s to keep it up off the floor.

Nat Puffer suggests a good place for a DME or transponder antenna is in the leading edge of the wing root. Simply hollow the wing leading edge out a little deeper, see Page 19-13, Section F-F. Do this similar to Section E-E on Page 19-14, and mount the antenna in the void.

Installation of side consoles. Make all of the side consoles and fit them, but do not install them at this time. Install all the fuel lines, wiring, rudder cable conduits, relief tubes, the control system in it's entirety, the landing brake and the pitch trim system, before you glue the side consoles in permanently.

VariEze Comm Antenna
This has been an ongoing problem, and several different antennas have been tried, some have been successful, but not on every airplane. The comm antenna on a Long-EZ is in the vertical winglet. Unfortunately the winglets on a VariEze are just not big enough. Mike DeHate has an excellent radio. We recently talked to him from over 100 nm away and he sounded as though he was on our wing. He has the following antenna: He cut an ordinary piece of house wiring to 20 1/4" long, and pulled two strands of copper wire out of this piece. These were inserted into a conduit which was installed on the trailing edge of the main gear. The center conductor of the RG58AU coax cable is soldered to the 20 1/4" length of copper wire that goes down the gear leg. The shield is soldered to the 20 1/4" length of copper wire that goes through the fuselage. Three ferrite beads are installed over the conduit per the sketch below. The beauty of this arrangement is that if it should break it is easy to pull out and replace. **SKETCH OMITTED**

Moldless vs Prefab shells for Homebuilt Construction.
We often get requests to provide molded shells of the Long-EZ to make it "easier to build". Our experience with molded shells has indicated that the full-core moldless structures provide more reliable structures without compromising building time. The most meaningful demonstration of this though, is actual homebuilder experience. Johnny Murphy, who has built four different moldless aircraft, recently completed a molded Glasair. His comments on relative simplicity are printed in the Spring '82 issue of Sportsman Pilot magazine. Sportsman Pilot is a quarterly with very quick response publishing of current homebuilt news. Each issue has a wealth of the latest happenings in the experimental world. Subscriptions are $7.50 a year, Box 485, Hales Corners, WI 53130.

O'Products, manufacturer of engine protective plug kits for Beech and Piper, are now offering similar kits for the homebuilder. Kits are presently available for the Long-EZ and can be custom made for the VariEze Long-EZ kits for aircraft either with or without a prop extension are being produced. They may also be ordered for either the "male" or "female" inlets. The 'A' kit (for aircraft with 3" prop extension) is priced at $85.95 and includes three plugs and storage bag. The 'B' kit (for aircraft with 6" prop extension) is priced at $124.95 and includes five plugs and storage bag. The storage bag fits snugly into the space behind the passenger's head and is available separately for $24.95 in red, blue and yellow Naugahyde. Add $10.00 to kit or bag price for special color bag. For further information, or to order contact:

Patrick O'Brien
O'Products Homebuilt Division
269 Marjori Avenue
Thousand Oaks, CA 91320
(805)499-7369

Aircraft Spruce is now stocking the AOA oil analysis kits for $8.95. The David Hoffman cockpit lights are in stock for $12.50 each. They are changing to Latex gloves instead of vinyl, same price and they will also be stocking cotton liner for the Latex gloves.

VARIVIGGEN NEWS
As promised in the last newsletter, all those who requested to be put on a list to talk to and help other Viggen builders, should by now have a copy of the list. Any other builders who would like to have their name, address and phone number put on the list, let us know. The list will only be mailed to those who are on the list. The sole purpose of this list is for mutual aid, both moral and technical among the Viggen builders.

Ken Winter who had his Viggen at Oshkosh last year in gray primer has been working hard getting it completely finished for this year. It is really looking fabulous, as Ken and Kay have really put a paint job on it. In Kay's words "it gives our Viggen a commanding appearance". Look for this beauty at Oshkosh '82.

Len Dobson is planning on being at Oshkosh, so we should have at least 3 on the flight line. Unfortunately Bernard Duneman had a gear failure. The left main gear folded up after a normal landing, and Bernard is now having to do some fairly major repairs. It is not certain if he will make Oshkosh.

Bernard's failure was caused by the MG4 beam collapsing and allowing the gear to fold. It turns out that the Brock-supplied MG4s were fabricated out of 1018 steel, and this material is too soft. This is what was called out to Brock and at the time it was thought that 1018 would be more than sufficient, however, based on what happened to Bernard as well as Len Dobson, we feel that the MG4s should be fabricated from 4130N steel, and heat treated to 150,000 psi. The MG4 on my Viggen N27MS are fabricated from 4130 and heat treated and with 530 plus hours, and over 600 landings there has not been any problem. In view of the above, we are recommending that any builder or flyer who has the Brock fabricated MG4s, should contact Brock and exchange the original 1018 steel MG4s for 4130 heat treated parts. This is a mandatory change and must be complied with before next flight.

N27MS flew to the Taos Hospitality Club Flyin, a distance of 636 nm (732sm), with Sally flying our Long-EZ in loose formation. Our true airspeed at 11,500 ft was 138 kts (159 mph) and the Viggen (180 hp Lyc.) burned 7.8 gph. Our ground speed going east was 150 kts. (173 mph) and coming back, fluctuated between 109 kts (123 mph) and 131 kts (150 mph). I was happy with the Viggen's high density altitude performance, we landed at Flagstaff, AZ (7000 ft elevation), Taos NM (7100 ft elevation) and Winslow, AZ (5000 ft elevation) and had no problems. I was solo in the airplane; had I been two place, I would have been more concerned. Any aircraft is affected by density altitude. My technique is to lean for best power and lift the nose wheel as soon as possible, then hold an attitude that keeps the nose wheel off and accelerate on the mains to about 90/95 kts. or at least 5 kts above best rate of climb speed. Then I pull it off and climb to at least 100 feet before retracting the gear. The gear is draggiest in transit and I find I lose most of my 5 knot excess speed and even a little altitude during the time that the gear is in transit. Of course, this only applies to high density altitude operations; the airplane is very normal at sea level and climbs quite rapidly. The SP wing makes a big difference and anyone planning to do most of their flying at high altitude airports, should seriously consider the SP wing.

Propellers: N27MS seems to perform best all around with a Ted's 69 x 69. This gives reasonable cruise, and still allows a good rate of climb. I also have a Ted's 70 x 70, which works well at sea level or thereabouts, but it is not a good choice to fly in and out of airports like Flagstaff, Aspen, Taos etc.

Viggen Plans Changes.
MAN-GRD. MG4 beams, fabricated by Brock must be replaced by 4130 steel heated treated parts.

LONG-EZ DOCUMENTATION

SECTION I - MANUFACTURING MANUAL - This is the complete education manual for composite materials and methods, also, the plans and construction manual for the entire Long-EZ except engine installation and landing-brake. The manual consists of a 180-page, bound 11" x 17" book plus 14 full size drawings. It includes many photos, over 800 drawings and 65,000 words. The builder is led step-by-step through the entire construction of the airplane, including electrical system, fuel system and finishing procedures. The manual identifies sources for all materials and all prefabricated components. A video tape is available covering all aspects of building the moldless fiberglass/foam sandwich construction. The tape covers the latest methods used to obtain the optimum weight, strongest fiberglass lay ups. This presentation will help both the first-time and experienced builder and attain quality aircraft workmanship.

SECTION II - ENGINE INSTALLATION - This is a set of drawings and construction for the complete engine installation, including mount, baffles, instrumentation, electricals, fuel, exhaust and induction systems, carb heat box and muff, cowling installation, prop and spinner.

OWNERS MANUAL - This is the required operations handbook and checklists, including normal and emergency operation, detailed flying qualities and performance charts, maintenance, maiden flight procedure, and pilot checkout, etc.

A video tape is also available which covers the weight and balance procedures, taxi tests and first flight.

LANDING BRAKE - Complete full size drawings for the landing brake device. This is the large drag plate that extends from the bottom of the fuselage for landing approach.

Check items desired.	Price, includes first class mail to U.S. & Canada	Overseas Airmail - U.S Funds

If you are building a VariViggen from 1st Edition plans you must have newsletter 1 through 34. If you are building from 2nd Edition plans you must have newsletters 18 through 34. If you are building a VariEze from 1st Edition plans you must have newsletters from 10 to 34. If you are building a VariEze from 2nd Edition plans you must have newsletters from 16 through 34. If you are building a Long-EZ you must have newsletters from 24 through 34.

A current subscription for future issues is mandatory for builders, as this the only formal means to distribute mandatory changes.
Reproduction and redistribution of this newsletter is approved and encouraged.

The RAF hangar is located on the west end of the flight line at the Mojave Airport, Mojave, Ca. approximately 80 miles north of Los Angeles. You are welcome to come by and see our aircraft or to bring in any parts for our comments. We are normally open from 8:00 to 12:00 and 1:00 to 5:00 on Monday through Friday and 9:00 to 4:00 on Saturday. Closed Sunday.
If you are planning a trip to see us, please call first to assure that someone will be here to assist you, since occasionally we are gone to flyins. When arriving at Mojave by car turn east at the Carl's Jr. restaurant to find the airport.

When writing to RAF send a stamped, self addressed envelope along if you have any questions. If you are placing an order, it's best to keep it separate from a request for an answer to a builder question. Mark the outside of your envelope "builder questions". This will speed up your reply.

RAF ACTIVITY
RAF has undergone several changes since Canard Pusher #33. Burt's new company Scaled Composites Inc. is officially off and running. Scaled's new building is going up rapidly next door to RAF. Roger Houghton and Doug Shane have both joined Scaled and Larry Lombard has moved to Task Research in Santa Paula.

This has left RAF with Burt, Mike and Sally, Trish Palmer and Michael Dilley, Michael Dilley was heavily involved in the construction of the Amsoil Racer. He is also an expert prop carver and is proving to be a very valuable asset. Both Michaels are presently hard at work drawing Solitaire plans. RAF is shooting for a target date of January 1983,

when we hope to have the Solitaire plans available. Prefab parts will be developed and should be ready about the same time. In between, development continues in the Solitaire's engine department. We have just installed our third engine, this one is a KFM 107E and it looks promising.

RAF has agreed to join with Voyager aircraft (Dick and Jeana) to build the Voyager. Work is currently underway. This will be an interesting project due to the very latest state-of-the-art technology being used. Voyager will be built at RAF and should be flying in the summer of 1983.

We are also developing a new, steerable nosewheel (fork and lower casting) which will be retrofittable to both VariEzes and Long-EZs. This project is in the early stages of development, so please don't call us for information. When it is successfully developed and flight tested it will be available from Ken Brock, perhaps around Christmas time.

Soaring Society Of America Homebuilt Contest
The final stage of the contest was held over the Labor Day weekend in Tehachapi, California. This was most convenient for RAF, since Mojave is only about 20 miles east of Tehachapi which allowed us to make an airborne arrival. Burt flew the Grizzly towing Mike in the Solitaire from Mojave, west over the mountains where Mike released and did a little soaring while Burt descended and landed at Fantasy Haven. Mike then flew a short arrival show including hammerhead stalls and loops before landing.

The Solitaire was very well received and closely examined by the large crowd on hand. We removed a wing to allow the judges to see how it was done. Two of the judges flew the Solitaire which was towed as a pure sailplane behind the Grizzly. The two judges, Einer Einervoldson and Walt Mooney flew the Solitaire in formation with a Schweizer 1-36 (a 31:1 L/D) and the Solitaire was faster and did not loose altitude as quickly.

On Sunday morning the judges' decision was announced. The Solitaire was declared the winner by unanimous vote.

During the three day weekend, the Solitaire was flown many times, self launching using the Normalaire Garrett two cylinder engine and by being towed both by the Grizzly and the Pawnee. After the contest, Mike self launched the Solitaire and flew back to Mojave. We have flown almost 50 hours in 78 flights. The longest flight was self launched, the engine then shut off and thermalled for two hours and 21 minutes. Eight pilots have flown the Solitaire at this time.

RAF-Developed Composites Fly In The NASA Space Shuttle
The structural components in the Utah State University "Getaway Special Package" (a student project) flew on the latest NASA Space Shuttle mission using the basic RAF composite construction methods almost exclusively. Long-EZ plans, Chapter 3 was the text used. RAF is proud to have helped the USU student package become the first and only package to be completed, accepted and flown.

Congratulations to Don Jones of Knoxville, Tennessee. Don's beautiful VariEze was selected to receive the Wright Brothers Award at the 1982 Dayton International Airshow and Trade Exposition. Don's VariEze also won an award at Oshkosh 1982 for Outstanding Workmanship. It really is an excellent example and Don deserves these prestigious awards.

OSHKOSH 1982
RAF was well represented this year at Oshkosh. Burt and Pat flew the Defiant via Salt Lake City and Wichita. Dick flew his Long-EZ and Jeana flew Mike's VariViggen. Michael Dilley and Doug Shane drove the van pulling a trailer with the Solitaire on board. Mike flew the Grizzly and Sally their Long-EZ. This was interesting as Mike trued out at about 107 knots and burned 10 gph, and Sally in the Long burned 3.6 gph, and that included occasionally flying circles around the Grizzly (literally!). Everyone arrived safely at Oshkosh, although this year we all had to skirt around and under low ceilings and rain.

There was an impressive display of Rutan aircraft featuring; 16 Long-EZs, 64 VariEzes, 2 VariViggens, 1 Defiant, 1 Grizzly, 1 Solitaire, 1 Cozy, 1 Gemini and 1 Amsoil Racer. This year was the first time for the Grizzly, Solitaire, Amsoil Racer, Cozy and Gemini. Cozy and Gemini are privately built derivatives using the flying surfaces of the Long-EZ. In addition to all of this, the scissor wing AD-1 from NASA was there. The AD-1 of course, was designed by Burt in 1977 and was the result of an unsolicited proposal to NASA by Burt in 1975. The AD-1 was flown every evening in the airshow by NASA test pilot Tom McMurtry.

The Grizzly and the Solitaire were flown in the fly bys and the afternoon airshows. The Solitaire flew under its own power and was towed by the Grizzly as a pure sailplane demonstrating its 32:1 L/D for the first time at an airport other than Mojave.

One of the highlights of the convention for RAF, was the gathering of all of Burt Rutan designs for a photo session in front of the announcer's stand. Eleven different aircraft types were parked in a loose circle around the NASA AD-1, while press photographers snapped hundreds of pictures. (see back page). **PHOTOGRAPH OMITTED**

After the incredible Oshkosh week was over, all the RAF folk pressed on home. The only change being that Burt traded with Mike and flew the Grizzly home, stopping at several small grass strips. Several times, while flying into the teeth of a 20 knot headwind, Burt was heard to mutter something about wanting his Defiant back! The annual trek to and from Oshkosh every year is a major undertaking for RAF and although it is always fun, it is also very tiring. It was good to be home and all had a safe journey.

The following EZ Flyers flew into Oshkosh '82. Our thanks to all of them for making it such a successful show. "Mom" Rutan pleads once again for photos of your aircraft for her book. She says "many thanks to all who have sent photos in, but I'm still missing a few!"

Kerrville, Texas Flyin
If you want to enjoy an easy going, no rush flyin, Kerrville is a must.
Mike and Sally flew N26MS with Bruce and Bonnie Tifft in the yellow
